

#### Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

#### Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

- + *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
- + *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
- + *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
- + Manténgase siempre dentro de la legalidad Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

#### Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página http://books.google.com

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

## INDEX TO VOL. XXI.

Α.

A.

ABYSSINIAN pump, useful application of, 241
Adjusting the tension of warps, 439
Aeronautical Society of Great Britain. 384, 408, 424
Aland's injector, fan blower, and exhauster, 158
Albin's self-registering compass, 223
American locomotives and rolling stock, 206, 228; Naval
Board, 282; ordnance, 179, 221; shipping returns, 56
Anemometer, on a new, 172
Aniline black, making and applying, 243
Appearance of a comet, 336
Application of liquid fuel to metallurgy, 343
Approaching transits of Venus, 300
Armour-plate question, the, 167
Artilderal production of ice and cold, 390, 402
Artillery experiments in America, 22
Atmospheric money-making, 307; train signalling, 97
Attack on the patent laws, 401
Australia, weather in, 282
Austrian tooth-cutting machine, 175

#### В.

BARRANS' self-acting steam hammer, 384
Bermuda floating dock, the, 367
Bertram's petroleum store, 85
Bevis' feathering screw, 406
Bingley Explosion, the, 451
Black Sea cables, 344
Black and Ward's machinery for twisting tobacco, 333
Boats in the navy, 245
Boby's horse rake, 69
Boiler flue cleaners, 433: inspection, 78 Boiler flue cleaners, 438: inspection, 78

#### BOOKS, NOTICES OF :-

BOOKS, NOTICES OF:—
Bourne's examples of modern steam, air, and gas engines, 364
Bremner's industries of Scotland, 363
Burgh's modern screw propulsion, 364
Campin's law of patents for inventions, 363
Carkill on sewage, 131
Ead's system of naval defences, 205
Fairbairn's iron and its history, &c., 363
Kneeland's annual of scientific discovery, or year book of facts in science and arts for 1869, 346
Leroux's treatise on the manufacture of worsted, 238
Page's chips and chapters, 364
Sandberg's elasticity, extensibility, and tensile strength of iron and steel, 346
Stanley on drawing instruments, 5
Wormell on geometry, 5

Bourne's auxiliary propeller for sailing ships, 307, 348
Breech-loader, new American, 105
Breech-loading rifle, Soper's, 130; Martini-Henry, 210, 361, 383; Roberts', 313; Wilson's, 98
Bridge over the Caledonian Canal, swing, 84; over the Thames, 349; over the River Dulnain, Highland Railway, 172
Brinsmead's pianoforte repeater action, 296
British Association, 388, 437; Indian Submarine Telegraph Company, 97 Bronze statue of her Majesty for Montreal, 310; statues, how to cast, 355 how to cast, 355 Building contracts, 443 Bullets, explosive, 51 Bullion and specie, 189 Bushby's pill machine, 299

#### C.

CABLE, French Atlantic, the, 454
Calcining furnaces, 89
Caps and cartridges, manufacture of, 57, 99, 130, 150, 254, 325, 381
Captian, floating of the, 241
Captian, floating of the, 241
Captive balloon, the, 361, 388
Cask-making machinery, 210
Casks, impervious, rendering, 67
Casella's self-recording anemometer, 371
Casting steel under pressure by use of gunpowder, 355
Centenary of the steam engine, 437
Centrifugal machine, improved, 441
Chalmers, James, 17; target, the, 115
Channel bridge, 317; railway bridge, 443
Channel bridge, 317; railway bridge, 443
Chandron's shaft-sinking apparatus, 350
Church's patent slide valves and pistons, 403, 422
Civil Engineers, Institute of, 43, 379, 398; and Mechanical Engineers' Society, 300, 361, 421, 454

Clark's system of intercommunication in railway trains, 49 Climate of Norway, 106 Clyde and New York, 1868, the, 135 Coal and iron on the continent, 199; in the United States, 414; works at Round Oak, 215; gas, on the methods employed in determining the commercial value and purity of, 262, 276; in Germany, 283 Coiled iron railway keys, 129; tube boilers, 134 Collecting and utilizing sewage, 271 Colliery explosions, 433 Combined engine and thrashing machine, 9; man engine and water lift, 423 Comparison between the Whitworth polygonal and the Woolwich studded projectiles, 316 Compensation for inventions, 176 Controlling the armatures of electro-magnetic induction machines, 371 Cope's tobacco press, 281 Copper produce, 65 Corn grinding, 50 EARTHQUAKE proof architecture, 229

CORRESPONDENCE :-Aerial navigation, G. Senecal, 197
Application of liquid fuel to metallurgy, A. J. Works,
391 Association of Foremen Engineers, E. J. Reed, 355; J. Association of Foremen Engineers, E. J. Reed, 335; J. Newton, 373
Bourno's whirl-wheel star pointer, E. Hunt, 283
Bridge, solid lever, H. C. W. 30
Bellecting armour plates, H. W. Reveley, 161
Deterioration of submarine cables, J. W. Blundell, 216
Edwards' train signals, John Edwards, 320
England's strength, J. G. Winton, 247
Explosive compounds, H. W. Reveley, 197; F. W. R., 179 England's strength, J. G. Winton, 247
Explosive compounds, H. W. Reveley, 197; F. W. R., 179
Grinding corn, H. W. Reveley, 70
Hand screw propeller for barges and boats, J. Dyer, 10
Herculcan feat, Detector, 301
Hydraulic buffers, C. E. Amos. 109
Horse power, J. G. Winton, 247
Inventors and inventions, G. B. Galloway, 51
London Association of Foremen Engineers, J. Rae, 373
Mining accidents, S. Horrocks, 11
Mysteries of "Hercules." Detector, 336
Nickel plating, F. O., 109
Nitrate of soda, Wm. Lloyd, 160
Nitrate of soda, Wm. Lloyd, 160
Nitrate of soda process, the, and Mr. Bessemer's process, F. C. Knowles, 264
Nursey's explosive compounds, H. W. Reveley, 159
Oscillatory movement of the earth, W. Saloway, 30
Perpetual motion, J. E. Russell, 216
Piston Packing, T. Craddock, 458
Preservation of fron ships, C. F. T. Young, 123
Revolving disc batteries for harbour and coast defence, G. J. Gunther, 11
Railway train communication, A. B. Brandram, 266
Saving life at sea, H. B., 373
Sea torpedo, the, John Harvey, 230
Sheathing iron ships, B., 320
Ships of war, J. G. Winton, 283; F. H. R., 301; J. G.
Winton, 320
Simple galvanic battery, J. Howard, 160
Smith's liquid fuel furnace, W. L. Wise, 142
Smoke consumption, Enquirer, M., 109; nuisance, G. J.
Richardson, 391
Stars, colour of. 51
Submerged tunnel, J. G. Winton, 161
Submarine cables, J. W. Blundell, 230
Sugar and starch machinery, Enquirer, 109
Tobacco machinery, Edward Field, 109
Twin gun, a, Vigilans, 230; H. W. Reveley, 216
Velocipede Institute, A. de Lavigerie, 336
War rockets, A. de B., 70
Cotton press engine, 86
Crispin boot and shoe machines, the, 387

Cotton press engine, 86 Crispin boot and shoe machines, the, 387 Crystai Palace, the, 455 Curricle fire engine, Merryweather's, 137

DARIEN ship canal, the, 185 Determination of atmospherical variations, 203; free oxy-Determination of atmospherical variations, 20 gen, 389
Dictionary of engineering, 117
Dip circle, 317
Doering's rock-horing machinery, 386
Drainage, systems of, 37
Dredger, the rotary, 277
Drilling machine, portable, 47; multiple, 456
Driving shafts, friction clutch for, 227
Dunn's duplex tyre lathe, 195
Durable composition inking roller, the, 317
Dynamite, 371

Е.

EARTHQUAKE proof architecture, 229
Edmunds case, the, 454
Edwards' system of train signals, 294
Electrical balance thermometer, 361
Electricity and telegraphy, 17, 118, 132, 152, 169, 225, 328, 382, 435
Electric telegraphy irrespective of telegraphic apparatus, 173, 191, 214; the signals, 390
Electro-astronomical experiments, 282
Engineering progress in India in 1868, 67
English, Indian, and Australian Submarine Telegraph Company, the direct, 203
Examinations in science by the Science and Art Department, 437
Exhibition at Utrecht, proposed, 245
Experiments with percussion caps, 334
Explosive compounds for engineering purposes, 102, 121, 140; for projectile purposes, 167
Exterior of houses, cleaning the, 271

#### F.

FARADAY and his scientific discoveries, 229; the proposed memorial, 451
Feed-water heater explosions, 137
Fire-engine, steam, for Valparaiso, 45; telegraphy, 318
Fletcher, L. E., on feed-water heater explosions, 137, 334
Floating centrifugal drainage pump, 121
Flower show at the Crystal Palace, 371
Foreign coal and iron trades, 135, 444
Foremen Engineers, Lendon Association of, 122, 134, 194, 248, 264, 426
French Atlantic cable, the, 415; traction engine, 105
Furness and Slater's dredging machine, 242

#### G.

GAS in Singapore, 317; referees, new instructions of the, 273
Gear-cutting machinery, 246
Gearing for paper-cutting machine, 9
Gold and silver, coating iron and steel with, 176
Government memorandum to inventors, the, 196
Gray's safety miners' lamp, 316
Great American Railroad, the, 89
Greenwich Observatory, 417
Guns for Russia, new 11-inch, 45: on the proof of, 329
Gunpowder hammer and pile driver, 388

H.

HACKLING machinery, 28, 48
Huncock's new screw propeller, 272; screw propeller
regulator, 58
Hayes' steam plough tackle, 154
Heat, latent, on, 42
Heaton steel process, 37, 117
Heavy guns, working, Scott, 64; pumps working in a slope
of 1 to 4, 195
Helm indicator, Read's, 18
Hematite iron ore deposits of Whitehaven, 108
"Hercules," the, 326; gun working machinery of the, 240
flerring's warming apparatus, 20
Heyer's bottle corking machine, 443
llighland and Agricultural Society of Scotland, 84
lligh-pressure steam launch with surface condensers, 25
"Hindostan," trial trip of the, 293
Hoe and Co.'s printing machine, 297
Holden's wool combing machinery, 407
Hoosac tunnel, the, 335
Horizontal condensing engine, 47; propulsion, 289
Horn's safety miners' lamp, 262
Hydraulic litting and pulling jacks, 119; presses, 368
Hydrogen as an illuminating gas, 203
Hyposometer, remarks on, 68

#### I.

INDIAN telegraphs, 290; fibres, 369
Indicator, Richards', 20
Indo-European telegraph, 254
Induction coil, the great, 271
Institute of British Architects, 354; the Iron and Steel, 455
Institution of Civil Engineers, 9, 43, 82, 313, 352; of Mechanical Engineers, 100, 331; of Naval Architects, 83, 214, 224, 235, 255, 272, 291, 310, 352
Instructions of the gas referees, 5

Improved method of manufacturing iron and steel, 157;
Morse ink printer, 208; slide rest, 315; smelting furnace, 120
Impurities in water, 352
Instruments used by the Kew Committee, 424
Ironclads, long and short, 256, 274, 298
Iron ships, preservation of, 77; piles, socket joints for, 455; smelting, carburizing, and purifying, 457
Isthmus of Sucz Company, 434

J.

JOHNSON'S brick-making machinery, 243

KEW Committee, instruments used by, 424 King's College, 59

L.

LAGOONS and marshes on the shores of the Mediterra LAGOONS and marshes on the shores of the Mediterra-nean, 158

Largest rope in the world, 226

Launch of a corvette for Japan, 275; of the "Volage" and the "Audacious," 171

Launching box, Edwards, 24

Laying culverts under the beds of rivers and canals, 397

Ledger's railway signal, 241

LEGAL INTELLIGENCE:

LEGAL INTELLIGENCE:—
Amory v. Brown, 427
In re Bates and Reigraves' patent, 391
Crossley v. Dixon, 142, 246
Daw v. Eley, 50, 301, 319
Edmunds v. Greenwood, 301, 319, 355
Pulvermacher v. Hammond, 408
Read v. Norris, 409
Sparagnapane v. Coombs, 230
The Roccliff, 355

The Roccliff, 355

Lewthwalte's patent magnetic steel sharpener, 264
Lighthouses and lanterns, 365
Light, zirconia, the new, 458
Liquid fuel, 171, 407
Livingstone, Dr., 289
Local attraction, 301
Locking miners' lamps, 426
Logotypes, on the use of, 239
London Association of Foremen Engineers, 23, 134, 194, 246, 335, 426; University, visit of working men's clubs to the new building of the, 454
Lord Palmerston, bronze statue of, 235
Luminous sea, 28

#### M. .

M.

MACHINE tools, 67; for making lucifers, 116; for producing cold, 402; for manufacturing pottery, 438; new type composing, 456
Machinery for manufacturing tobacco, 80
Magneto-electric alphabetic telegraph, 314
M'Lintock's metallic packing, 107
Manchester Boiler Association, 108, 177; Steam Users' Association, 195
Manufacture of caps and cartridges, 57, 99, 130, 150, 254, 326, 381; of extract of meat, 10; of gas, 366
Marble polishing machine, 101
Marine disasters, causes and prevention of, 88
Martini-Henry rifle, 210, 361, 383
Marsden's tube joint and tunnel scheme, 279
Mauritius railways—Midland Line, 438
Meteorological Society, the, 153, 226, 327; research by aid of the electric telegraph, 273, 345
Metropolitan improvements, 59; District Railway, 264
Microscopical examination of dust, on the, 189
Midland Boiler Assurance Company, 246
Milliary arm of the future, the, 88; engineering operations, 295
Miller's angular drilling machine, 193
Minerals and metals, 48
Mining primers, 240
Miscollanea, 11, 31, 62, 71, 90, 110, 124, 142, 162, 180, 198, 216, 230, 248, 266, 284, 302, 320, 337, 356, 374, 392, 409, 427, 446, 459
Moodoy lightship, 420
Morton's ejector condenser, 102 446, 459 Moody lightship, 420 Morton's ejector condenser, 102 Mountain locomotive, design for a, 454

NAIL trade in the Midlands, 318
Naval architects, institution of, 83; military and gunnery
items, 11, 31, 52, 70, 90, 110, 123, 142, 161, 180, 197,
216, 230, 247, 266, 283, 302, 320, 336, 355, 373, 391, 409, 427, 216, 230, 241, 420, 260, 522, 445, 488
Astional Boiler Insurance Company, the, 212
Natural gas, 88
New bridge at Niagara, 51; deadly weapon, a, 426; decorative material, 367; life-saving apparatus, a, 426; lime-kiln at Ingleton, the, 141; steam stamp mill, a, 88; type-setting and distributing machine, 444; uses for paper, 326; York Society of Practical Engineering, 10, 29, 43

 43
 Nitrous oxide gas to prevent pain, 107
 Notes on our navy, 400, 168; on recent scientific discoveries and their practical applications, 20, 39, 60, 81, 100, 119, 132, 152, 170, 206, 225, 239, 256, 292, 311, 329, 346, 364, 382, 400, 419, 436, 453 Nurse's apparatus for finishing tinned plates, 332

O.

ORITHARY :-

CHALMERS, James, 17 Ellis, Sir Henry, 70 Graham, John, 159

Occultator, on the, 370 Official trial of the liquid fuel plate furnace at Chatham, Onicial trial of the Manager 24 of 407
Optical experiment, 40
Outfall of the Humber, 347
Outfall of sequilibrium slide valve, 193, 209
Owen's steam pumping engine, 245
Oxides of chromium and titanium on pig iron, influence

P.

PACIFIC Railway, 444
Palmer shell, the, 89
Panama hats, 247
Parliamentary notes, 153, 170, 188, 206, 225, 292, 311, 329, 347, 364, 419, 436, 453
Passenger engine, four-wheel coupled, 226; locomotive engine, 9
Past year, 1
Peace jubilee at Boston, U.S., 448
Permanent magnet, on a new form of, 155
Pemberton's improved Rodman gun, 351
Phenomena of light, 179; of magnetic storms, 383
Phosphates in agriculture, 65
Photography, 4, 79, 169; improvements in, 19
Plak colour, on the causes of, in white lead corrosions, 455
Piston packing, 438
Portable engine, 9; printing press, 335
Preparing cabinet specimens, 65
Preserved meat, 236
Preparing cabinet specimens, 65
Projected Mersey tunnel and railway, 372
Proposed abolition of patents, 383; patent laws, 397; new works for the navy, 196

#### R.

R.

RAILWAY bridges, permanent way of the Thames, 44
Rainfall in Cornwall, 50
Range experiments for field artillery at Shoeburyness, 390
Ransome's general joiner, 313
Rateable and non-rateable machinery, 117
Read's helm indicator, 18
Recent earthquake shocks, 282; launches, 209, 437; heavy storms, 135
Recovery of soda v. river pollution, 149
Rethning process, improved, the, 452
Referees, gas, report of the, 451
Refrigerating apparatus, Wilkins', 133
Registering the force of the wind, 196
Relation between meteors and comets, 229
Re rolling old railway iron, 176
Reversing stations, 185
Richards indicator, 20
Rickard and Paul's amalgamating machine, 352
Rigg's horizontal oil agitator, 227
River Plate, emigration to the, 455
Roberts' breech-loader, 313
Rodman gun, 276
Roll apinning by machinery, 118
Rotary arming press, 69
Royal Botanic Society, 86; Hortleultural Society, 347, 416; Institution, the, 45, 186, 204, 223, 272, 290, 309, 328, 363, 381; National Lifeboat Institution, 125; United Service Institution, 135

SAFETY nitro-glycerine, 204
Sanitary condition of our navy, the, 115
Saving life from shipwreck, 65
Science for the people, 419
Screw propeller regulator, Hancock's, 58; propulsion, 435
Sea torpedo, the, 212
Scif-acting punkah, 107; feeding envelope folding machine, 260
Scwer ventilation, 237
Scwer ventilation, 237
Scwer ventilation, 237
Scwer ventilation, 237
Shaw's improvements in looms, 175
Shell experiments at Dartmoor, 434

Shipbuilding on the Clyde in 1868, 43 Ship canal, the proposed Huron, 179 Shoeburyness, recent gunnery experiments at, 253 Size for dressing cotton yarns, 444 Smithfield Club Show, 20 Smith's liquid fuel furnace, 115 Smith's liquid fuel furnace, 115
Society of Arts and the patent laws, the, 82; Engineers, 62, 415, 438
Solway viaduet, 50
Soper breech-loading rifle, the, 130
Spanish international exhibition, a, 380
Statistics of boiler explosions, 367
Steam boiler explosions, 365; hammer for the Russian government, 139; pile driver, 168; pumps, 384; snip-building on the Clyde, 197; r. horse power, 246
St. Thomas's Hospital, 60
Stirk's attemperator for union casks, 407
Stone dressing by machinery, 155
Storing petroleum, 78
Storm signals, 129
Street bridges, 343; tramways, 187; tunnel at Chicago and its machinery, 389
Submarine lamp, 24; cables, submersion and recovery of, 442 442 Swann's hot air lime kiln, 331

TANK locomotive, a new, 215
Telegraphic literature, 188
Telegraph wires in architecture, 63; prospects, 39; Anglo-Mediterranean, the, 452
Temperature of 1864, the, 123
Temporary structures, 221
Textile fabrics, printing, 30
Thermodynamics, founder of the science of, 209
Thrashing apparatus, self-feeding, Hambling's, 41
Titaniferous iron sands of Canada, the, 89
Tower sulway, the, 204
Traction engine, a new, 354
Triat of the "Inconstant," 367
Tube sheet, the, 339
Tyndall, Professor, on chemical rays, 57; researches on light, Dr., 129

UNIVERSITY of Glasgow, 334

v.

VENTILATION, 244, 280, 317 VENTILATION, 244, 280, 317
Velocipedes, 308
Velocipede railway, a, 169
Vertical drilling machine, 107
Vinduct, Solway, 50
Victoria, emigration to, 275
Visit of the Civil and Mechanical Engineers to the Thames
Embankment and St. Thomas's Hospital, 300

#### W.

W.

WALKER'S atmospheric tun room attemperator, 190
War rockets, remarks on, 50, 85

THE

#### MECHANICS' MAGAZINE.

LONDON: THURSDAY, JANUARY 1, 1869.

THE PAST YEAR. GENERAL RETROSPECT.

N commencing our annual review of the occurrences which have marked the scientific progress of the past year, we are struck with the absence of any results which stand out more prominently than others, or of any circumstances that impart to the year just closed any special lustre. Progress there undoubtedly has been, but it has been slow; things have been going on very coberly and quietly, and although we looked forward this time last year with hope to a cessation of that stagnation under which trade and commerce had for long laboured, our hopes have not been realized. That engineering is still at a low ebb is a plain fact which cannot be dis-guised. But there are some signs of returning vitality at home amongst our manufacturing engineers, and abroad there appear to be works upon which we hope the new year may see some of our civil and mechanical engineers England, it would seem, has had a surfeit of railways, and for the present we cannot hope that much will be done to add to their mileage. But we look to the future for a further development of our railway system, as well as to an extension of our dock and port accommodation. In the meantime, there are unmistakeable signs of work abroad, especially in India, where greatly needed irrigation and storage works, on a gigantic scale, are proposed. Here, indeed, is a field for en-In Central India there are nearly 124,000,000 acres to be irrigated; in Hindostan 1,500,000 acres still crave water; in the Mysore district the old native structures are being disinterred with a view to their restoration to use; the flood canals in Scinde are to be converted into perennial streams; a tank, to cost £90,000, is among the works now going on in the Deccan; two canals leading to Calcutta are to be made-one from the coal mines of Raneegunge, the other from the Ganges at Rajmahal; another, from the Jumna, near Delhi, will water the Muttra and Agra dis-tricts; and the Sutlej Canal, first projected in 1861, is now to be put in hand. To these matters, then, we commend the attention of the engineering profession, and if it can only succeed in awaking the capitalist from out of his lethargy, it will reap a rich reward.

We have said that there was no startling circumstance or discovery to mark the year just past. True, there was not; but none can say how nearly there may have been in Captain Ericsson's wonderful solar engine, which under the head of "Bottled Sunshine," we discussed at page 321 of our last volume. The latest intelligence in this direction is, that M. Mouchat, who has been experimenting on the utilization of the solar heat, sent a paper on this subject to the Academy of Sciences. He states that, according to his experiments, upwards of three-sixths of the solar heat might be gathered at a small cost. At Paris, a surface of one square metre normally exposed to the rays of the sun receives, on an average, at any time of the year, on a fine day, ten units of caloric per minute. Such a quantity of heat would make a litre of water at freezing point boil in ten minutes, and is equivalent to the theoretical action of a one-horse power. He further states that he had proved the possibility of keeping hot-air machines a-going by means of solar rays, and had succeeded in making a few litres of water boil by exposure to the same agent; and in June, 1866, he had made a small steam engine work by convert-

June, 1869, that either Captain Ericsson or M. Mouchat will have succeeded in utilizing this power to some useful purpose, but we, nevertheless, do not expect it.

Proceeding to more practical matters, we may first refer to the establishment of works for making steel by the direct process discovered by Mr. Heaton. There has been much discussion upon the practical results of this invention, but its success is unquestionable, and we believe the introduction of the process marks an era in our steel manufacture, upon which Mr. Heaton is to be congratulated. The question of technical education has been prominently before the public during the past year, and has received an impetus in the benefaction of Mr. Whitworth, which will bring forth fruits for all time. Mr. Whitworth has done much to promote the engineering interests of the country, but this unselfish and noble-minded act places his professional achievements in the shade.

Metropolitan improvements have made considerable advance during the year. A magnificentmeat and poultry market has been recently opened; the Holborn Viaduct has progressed satisfactorily; the Thames Embankment has been opened to the public from Westminster to the Temple, and its continuation to Black-friars Bridge is progressing. An untoward accident, however, will retard the works on this section, the completion of which will, therefore, be delayed beyond the contemplated period. The new bridge at Blackfriars has for some time past presented a very forward appearance, the ribs being in place from end to end of the structure. Three of the arches have the spandrils filled in, and the parapets are fixed to two arches. The cross girders and roadway bearers are fixed over two of the arches ready to receive the buckle plates. We believe that if no accident arises to interfere with the works, this splendid bridge will be opened to the public in June next. land Railway terminus at St. Pancras, which is covered by the largest roof in the world, has been opened, and the public have the opportunity of inspecting one of the finest ieces of roof construction of the day.

From railway stations to railway trains is an easy transition, and here we have to notice the successful trial of several methods of communicating between passengers and guards in railway trains during the year. These have been based chiefly upon the electrical and the pneumatic principles. As the time approaches when such communication will be enforced by law, it behoves our railway officials to be up and doing, or they will find themselves unprepared to meet the requirements of an Act of Parliament by the time they are called upon to pay the penalties it exacts.

In gunnery matters we have to note the recent success of the Whitworth gun in accomplishing a range never before reached. Mr. Whitworth is to be congratulated upon this result, but we look for further experiments to test the penetrative powers of this weapon. The Millwall shield, designed by Mr. Hughes, of the Millwall Iron Works, nas most successfully borne the brunt of a heavy fire with Palliser shot, and has set us thinking what turn the question of guns v. targets will assume during the coming year. The commencement of last year found the guns-thanks to Major Palliser's chilled projectiles -victorious; the commencement of the present year finds the targets—thanks to Mr. construction and metal-in the ascendency. The Moncrieff system of serving guns in forts, and Captain Scott's method of training them on board ship, have been proved to be very successful, and to embody the principles demanded by the present positions of military and naval gunnery.
In small arms we have no actual result as

far as regards the definitive official adoption of any one system out of the many which entered into the Government competition. The Henry rifle undoubtedly carried off the ing water into vapour with the assistance of reflector one metre square. We hope by palm, but whether it will be finally adopted other than those to which we have been re-

as the military arm of the future appears at present uncertain. Unless a better system can be produced—and we doubt whether it can-it will be an act of injustice to Mr. Henry if his arm be not introduced into the The small-arm cartridge public service. question was settled by Mr. Daw receiving the £400 prize, but here the matter rests. We cannot, however, understand why, if this cartridge was acknowledged to be the best out, it should not supersede the present service cartridge. We, some months since, proved that it possessed qualities which rendered it superior to the service cartridge, and certainly expected the authorities, in the fulfilment of the trust reposed in them, would adopt into the national service the best cartridge they could find.

Gunpowder is so closely allied to gun cotton that we naturally turn from the one to the other. Here we find a marked improvement to have been introduced during the past year. This consists in rendering this dangerous material safe in case of accidental ignition in any other condition than that of actual use. By Professor Abel's pulping process, and a peculiar method of treatment introduced by Messrs. Prentice, this firm are now producing a material which will not explode except in a closely confined position. We recently burnt a large wad of this material on our hearth, which, if it had been made under the old system, or if it had been enclosed in a resisting material, would probably have re-moved ourselves and our office to another part of Fleet-street, and in a most summary manner. As it is, experiments with this gun cotton have so convinced railway managers of its safety that it is now carried on some lines at the ordinary goods tariff. While on this subject, we must not pass by Mr. Nobel's splendid improvements upon that frightfully dangerous compound—nitro-glycerine. What Mr. Abel has done for gun cotton, Mr. Nobel has effected for nitro-glycerine. He has, in effect, tamed it, and although the most startling results are produced from the new material—dynamite—when fired with a special fuse, when fired in the ordinary way it is as harmless as the same quantity of sawdust. Some advance has been made during the

past year towards solving the question of using petroleum as a fuel on board steam vessels. On land it has for some time past been in use under boilers, being burned in several different ways. But it remained for Mr. Dorsett to demonstrate the practicability of successfully working a ship of 500 tons burthen with mineral oil. Although the application was comparatively rude, and the apparatus capable of considerable improvement, the experimental trips with the "Retriever," a month or two since, left no doubt as to the efficiency of the system, and, taken all in all, it was the first success of the kind on such a scale—that we have had. Messrs. Wise, Field, and Aydon's system of burning liquid fuel is being adapted to a large vessel, and we hope soon to hear of some results. The application of gas to the generation of steam, upon Mr. Jackson's system, has been perfectly successful wherever it has been tried. Mr. Jackson, the successful exponent of this system, has put down several of his gas furnaces during the past year, and, judging from the favour they meet with, we doubt not but that he will put down many more in the year now before us. We have not remarked that any progress has been made during the past year in solving the question of peat fuel—that is, in producing it in such a form and at such a price as that it may become a staple commodity in the market. We have no doubt of its great value for many purposes, and trust its merits will not be lost sight of. A fortune lies before the man who successfully utilizes the enormous deposits of peat Great Britain and Ireland contain.

Whilst men have been working ferring. busily in the visible world, death has been busy too, and has removed some of them from amongst us to the invisible world. During the year just closed, there have passed away from us several distinguished labourers in the fields of science, and others who had carned for themselves a name by their pro-fessional prominence. Amongst the first of these stands Sir David Brewster, who died on the 10th of February last, at the ripe age of eighty-seven-"full of years and honours. On the 27th of the same month died Mr. Michael Lane, long connected with, and of late years the engineer-in-chief of, the Great Western Railway. Mr. Stewart, the chair-man of the Anglo-American Telegraph Com-pany, died a few days later. The 7th of May saw the close of the career of a great man-Henry Lord Brougham-who, during his life, often entered heartily into matters of science, and with whom one of the founders of the MECHANICS' MAGAZINE was associated in the establishment and promotion of mechanics' institutions. The 20th of November saw institutions. the death of Mr. John Robertson, the maker of the engines of the "Comet," the first vessel that steamed on the Clyde. The "Comet" was the first steamboat that plied on European rivers for practical purposes, and Mr. Robertson was the first engineer (out of America) who permanently succeeded in adapting steam to the propulsion of vessels on rivers for purposes of actual traffic. Our latest loss has been that of Mr. James Chalmers, a gentleman whose name is well known to our readers, and who died on Saturday last. Mr. Chalmers was the inventor of the target which bears his name, and the projector of the Channel railway to connect the shores of England and France. It will be remembered that some of the experiments at Shoeburyness proved that the guns had obtained a victory over Mr. Chalmers' target. As, however, Mr. Chalmers had improved his system, so as to meet the requirements of the times, a second target was ordered by the authorities, and is just ready for further experiments. We regret to find that Mr. periments. We regret to find that Mr. Chalmers leaves a widow and family in straitened circumstances, and we hope the Government will make them some acknowledgment of Mr. Chalmers' efforts to serve his country.

And now, having touched generally upon

those matters which have come with more or less prominence before our readers within the last twelve months, we shall proceed to notice, at greater length and under distinct heads, such special subjects as have been more fruitful of results than the majority of those we have been discussing. And first we shall refer to-

#### NAVAL ARCHITECTURE.

THE shipbuilding of the year has not been remarkable in so far as mercantile steam vessels are concerned, unless the losses of the "Hibernia," the "Borderer," the "Gossamer," and other vessels, with their various degrees of horror, may be considered to give the subject a tragic interest. It is much to be feared that the keen competition of the Clyde and Tyne builders is leading to the increased production of cheap ships under lax conditions, and it will no doubt become a serious question ere long as to how far the Board of Trade is fulfilling its duties. We think there is ground to apprehend that the superthat department of the Government is gradually being narrowed down to a mere inspection of outfit, and that with the abandonment of the former requirements, in reference to water-tight bulkheads, other important structural considerations have been also abandoned. It cannot be denied that many iron ships are now built with nothing but a thin, and often bad, shell of iron to keep the passengers and cargo afloat, the collision bulkhead forward being all that is attempted in the way of water-tight subdivision of the expect to be in possession of full and authentic to the Government. This change has been interior. Mr. John Bright, M.P., the new information respecting the merits of all the throughout advocated by us, and we still feel

President of the Board of Trade, while shrinking from the control of the military of India, would certainly do well to turn his attention to the question which we have felt it our duty to raise here, and to see if he cannot prevent a portion of that annual loss of life and property which is brought about by imperfections in our ships. It is a task well worthy the efforts of a humane statesman.

One of the most striking facts in connection with the mail ships of the highest class is, that the Clyde has at length drawn the work of the Peninsular and Oriental Company away from the Thames, and in yielding to this the company have secured, we believe, both better and cheaper ships—better, not in point of workmanship or material, but of design, and in particular in the power of carrying their ports and side-lights well above the sea. The "Bangalore" and "Sumatra," both built by Denny, of Dumbarton, were great improve-ments upon the later Thames-built ships in this respect, the Thames firms having unquestionably run into extremely fine hatchet ends without compensating fulness at the middle body. The "Deccan," the last of these fine vessels built by Denny for the Peninsular and Oriental Company, is probably the very best ship in their fleet.

The nearest approaches to ships of the passenger-carrying class of mercantile steamers among the ships of the Royal Navy are the Indian transports, which are now performing their second season's work. In so far as the ships themselves are concerned, they are universally admitted to be the most efficient and commodious ships afloat; but the same praise cannot be given to their engines, of which those made for the "Jumna" by Maudslay and Field, and those for the "Scrapis" and "Crocodile," by Humphrys and Tennant, have proved the least satisfactory. be borne in mind, however, that the service required of these engines is very continuous and very trying for several months of the year together, and it appears to us more than probable that the engineer staff of these vessels is insufficient for the proper working of such complicated machines as the modern type of engines, working at high velocities for long

The war shipbuilding operations of the country have been remarkable during the past year. Messrs. Napier, of the Clyde, and Messrs. Laird, of the Mersey, have sent their Dutch monitors to sea, or, rather, have sent them home to Holland successfully; and Messrs. Napier's ram, "De Buffel," has likewise been completed and sent away, and availed herself of an early opportunity of proving that she, at least, although a turret ship, could roll as effectually as any broadside ship in the world. The turret ships "Capship in the world. The turret ships "Captain" and "Monarch" are approaching completion; so also is the monitor "Cerberus." The fast-flying frigate, "Inconstant," and the fast-flying corvettes "Volage" and "Active," will all be ready in the spring; and the pon-derous armour-clad "Hercules," with her with her extremely thick armour and 18-ton broadside guns, has had her bottom finally coated at Portsmouth, preparatory to her measured mile trials, after which she will forthwith proceed to test her qualities at sea. dacious" is to be launched a few weeks hence, and will at once be engined and completed, so that she may be got to sea in the course of a few months. This year will therefore be a most fruitful and interesting period of naval experience, Captain Coles sending forth his type and exemplar of a perfect sea-going turret ship, and Mr. Reed, the Chief Constructor, sending out not only a specimen sca-going turret ship, but also a specimen coast monitor, a specimen ironclad broadside frigate of the most powerful class, a specimen unarmoured frigate of extreme fleetness, and a specimen unarmoured corvette of like character. By the end of this year, therefore, we may fairly

leading types of modern war ships, and when the estimates of 1870-71 are prepared, Mr. Childers will have much ampler knowledge to proceed upon than any of his predecessors have possessed, or than he himself now has to guide him in preparing the work of next year.

The publication of a technical work upon iron shipbuilding, by the Chief Constructor of the Royal Navy, is a circumstance deserving mention here. Our review of this work, published in two successive numbers a few weeks ago, precludes the necessity for present comment; but it will be interesting to our shipbuilding readers to learn that this work has already been widely purchased in France, Prussia, Russia, Italy, and America, and proposals for its translation, in extenso, into the French and Russian languages have been made to the English publishers. The reception of the work by the profession in this country has been all that we predicted.

#### ELECTRICITY AND TELEGRAPHY.

In our remarks at the beginning of the year, we looked forward with some hope to greater telegraphic extension as a consequence of the renewed confidence in financial matters, and it is a matter of great congratulation that our hopes have been more than fulfilled. In telegraphy itself, many great and useful enterprises can be welcomed as not only undertaken, but carried out, during the past year, but also others which have been undertaken and are still in progress. Amongst the latter, is one which naturally claims our foremost attention, although, in our last summary, we looked forward to it as being one of the successes of the past year. It cannot yet be ranked as such, but it remains for the year ranked as such, but it remains for the year 1869 to complete the good already done. The acquisition of the electric telegraphs of the United Kingdom by the Government, and their being placed under the Post-Office administration, is alluded to. The question is one that had been mooted for some time, but, in the present spring, action began to be taken and enquiries made; the result has been a large correspondence and crossfire of pamphlets between Mr. Scudamore, of the Post-Office, on the one hand, and telegraph companies on the other. This cleared the way for the Government Bill, which, after being committed, and much time spent in discussing and amending its objects, finally passed both Houses of Parliament, and became law. empowered the Post-Office to buy up all the telegraph systems of the various telegraph companies of this country who were willing to sell their property. This all have been to sell their property. This all have been found willing to do, and meetings have been held authorizing the directors to agree to the Post-Office terms, which have been usually a twenty years' purchase on present rates. The final amount to be paid to the various telegraph companies has to be settled by arbitra-Agreements have also been entered into between the Postmaster-General and the various railway companies, by the which it is settled that all wires belonging to the railway company, and used by them for their special services of train signalling or otherwise, shall remain theirs, in addition to which the railway company will in future maintain all wires, poles, and telegraphs, the property of the Government, passing over their lines. Under this arrangement, there may be perceived the following curious change-what the telegraph companies formerly did and still do for the railway companies the railway companies will now do for the Government.

The Post-Office are making great internal changes preparatory to taking charge of the telegraph system, and to complete the transfer it is now only necessary to bring into l'arliament the bill for providing the necessary funds. It is anticipated that this will be done very early in the year, and by July 1 it is most probable that the various telegraph companies will have handed their systems over confident that the change will be beneficial to the general community.

The electric and telegraphic world has had a great compliment paid to them during the year by the knighting of Professor Wheat-stone. There are few men who have done, and who are still doing, so much good for telegraphy, and it is to be hoped that Sir Charles Wheatstone may live long and add more to his numerous inventions for improv-

ing telegraphy.

The French Atlantic cable is one of the enterprises of the year undertaken but not completed. Our columns lately have given completed. details of this work; suffice it to say that, by this time, about 700 miles of the deep sea cable are completed, and the shallow water cable and the heavy shore ends have been commenced. The work of fitting up the "Great Eastern" is satisfactorily going on, and early in January the first shipment of cable will take place. In fact, everything promises to be so forward and in such a completed state, that the "Great Eastern" will be able to leave our shores by July 1 next. It is to be trusted that, soon after that date, we shall possess another link in the chain to bind us to our transatlantic brethren.

Another important enterprise commenced and not completed during the year is the new Indo-European line. The object of this line is to carry two overground wires from Nordeney, on the Hanoverian coast, through Prussia, Russia, via the Black Sea, and through Persia to Teheran, where it will join the existing system belonging to our Government. From Nordeney to Lowestoft, wires are leased in the cable belonging to Reuter's Telegram Company, and from Lowestoft to London by the Electric Telegraph Company's system The whole scheme has been started from valuable concessions obtained from the various Governments by the Messrs. Siemens, who have surrendered their rights to a company called the Indo-European Telegraph Company. The entire works are being carried out by the Messrs. Siemens, and it is confidently anticipated that the whole system will be in working order towards the close of this year; this will then furnish us with another route to India.

A long step in the direction of another route to India has been undertaken and completed during the past year by the Anglo-Mediterranean Company, which was formed for the purpose of purchasing the line constructed by the Telegraph Construction and Maintenance Company from Susa, on the French-Italian frontier, to Modica, in Sicily, and for laying from Malta to Alexandria a direct deep sea cable. The whole of this work has been completed, and the line is now in perfect working order. The land line has been completed and handed over, a submarine The land line has cable laid across the Straits of Messina, and the deep sea cable of about 920 miles successfully submerged by Sir Samuel Canning between Malta and Alexandria. The submergence of this cable lasted some little time longer than usual, in consequence of two accidents happening during the paying out. A foul-flake occurred, when a quantity of cable was brought up in a bunch, but by quickly stopping the vessel, the mass was disentangled; and the vessel proceeded on her course until a kink occurred some time after; this unfortunately, however, gave rise to a slight fault. The vessel was stopped, and the cable picked up, the bad place was cut out, and the cable spliced, and all proceeded satisfactorily to the landing of the end. This cable is worked in a manner similar to the Atlantic, by the use of Thomson's reflecting galvanometers.

A cable of 340 miles in length was laid during the year by Messrs. Newall and Co., from Sondervig, on the Danish coast, to Newbiggen, near Newcastle, for the Danish, Nor-wegian, and English Telegraph Company. The special feature of this cable was the substitution of Hooper's india-rubber for gutta-

percha as the insulator. The cable works in

the most satisfactory manner.

We have yet a great many things to notice under this head, but want of space obliges us to defer the remainder of our remarks until next week.

#### ELECTRO- METALLURGY.

In the year that is just ended but little has been added to our knowledge of the laws of the electro-deposition of metals, and not a great deal to the application of those laws which are already known to the arts of electrocasting or electro-coating; still, some progress has been made, and especially in the improvement of some of the modes of carrying out these arts. Last year we noticed a new application of electro-coppering, as applied to the coating of ships for the pre-vention of fouling and corrosion, which had then but newly been tried, and we were then in hopes that by its means copper would soon be successfully applied to the bottoms of ships for their protection, but yet little progress has been made in that direction. that a firmly-adhering coating of copper cannot be applied to iron; we have seen this done repeatedly, but the difficulty is in applying it to ships. As we have pointed out repeatedly, this cannot be done to ships' plates before being built into the ship; there are the rivets, which must be coppered also—yet, if coppered, how are they to be riveted? It is impossible. Even if ordinary copper rivets were admissible on the score of cost and strength, they could not on the score of electric action. For if they contained lead, as almost all commercial copper does, they would become electro-negative to the electro-plastic copper, and so assist to destroy the coating of the plates. It is true that electro-plastic copper could be made into rivets, but this would be at double the cost at least, and this would enhance the price enormously, the rivets required being both very large and numerous. But besides these considerations. copper rivets would not be strong enough. Are we, then, to give up all hope of coating iron ships with copper? By no means; but it will not be by the direct application of the copper to the iron. We think the difficulties of such a process are too great to be successfully overcome. The process which appears to us most likely to succeed, is to coat the plates of iron with copper by electrolysis (the iron giving strength), and with these plates to sheath the bottom of the ship, between the sheathing and the ship an insulating substance being interposed. Of course, in this way, a ship could be sheathed with ordinary commercial copper, but the sheets would have to be of sufficient thickness to prevent buckling and bulging from the insulating material, so that with plates wholly of copper the sheathing would be six or eight times the cost of that we have hinted at. We should like to see thin iron plates coated with copper, applied as sheathing on a large scale. have seen it tried on a small one, and have but little doubt of its success on the large.

In electro-casting in copper there is nothing new to take note of; indeed, there seems scarcely anything to be desired in the results already obtained. In electro-coating with already obtained. In electro-coating with silver, as applied to copper, brass, and German silver, there is nothing new; but we are sorry to find that there is something new with regard to the coating of the alloy of lead and tin (common soft solder) with silver. Not that this practice has originated within the last twelve months, but it has become much more extended, to the loss of purchasers of plated spoons and forks. This is a deception and a cheat. The forks and spoons are roughly made of a common kind of German silver, or, rather, a highly speltered brass, without a particle of nickel in it, and then coated with common solder by immersion in the melted metal; they are then easily rubbed down smooth, and the expense of filing, 500deg. Fah., so as to fix the silver, and burnishing, and polishing saved, and this is after that it will stand a red heat without

the reason why this practice has been resorted There certainly is more difficulty to the ordinary practitioner in coating this alloy with silver than in coating German silver, The same method cannot brass, or copper. be pursued with this alloy as with the above metals. Mercurial cyanide or nitrate is of no avail to prepare it for the silver; instead of this as a preparation, the spoons or forks are suspended in a boiling solution of caustic potash or soda for a short time, and then transferred quickly to the silver cyanide solution, to which is attached a strong battery, so that they may be quickly coated with silver, and the action of the cyanide solution on the alloy is prevented by rendering it strongly negative. When they are coated they look as well as other spoons and forks, but they soon chip, owing to the softness of the alloy under the silver, as well as the imperfect adhesion of the silver to the alloy. This is a disreputable practice, because the inferior article cannot be known from the superior, except in the wear, when it is too late. We are sorry that it has much increased of late.

There is another branch of electro-coating, wherein some progress has been made during the past year, that is the coating of iron, steel, and cast iron with copper and silver. make silver to adhere firmly to iron and steel has been a desideratum much sought after for many years; indeed, ever since electro-plating was discovered. It has always been found much less difficult to make copper adhere to iron than to make silver adhere to it; consequently, it has hitherto been the practice to coat common dessert knives and nutcracks with a thin coat of copper and then with a coating of silver. But these are much inferior to the solder-plated knives, called close plated, which is a thin sheet of silver soldered on to the blade with common solder. These are called the best plated knives, though plated with soft solder, because hard or silver solder is not applicable to plating knife blades, on account of the heat necessary, but to carriage harness and coach fittings hard solder plating is applicable, but its expense prevents it being much used. This new process referred to above is equal to hard solder plating, but cheaper than soft solder plating. The inventor of it calls it pyro-plating, because the fixing of the silver is done by heat, as also the preparation of the articles for silvering. We noticed the first approach to this process some four years ago, when a patent was taken by the inventor, Mr. J. Baynes Thompson. In the specification of that patent is described the process for obtaining a pure surface, whereon to deposit the silver, and this was by depositing a film of iron on the article. But within the last six months the same gentleman has taken out another patent and abandoned the previous one. In this new process there is no intermediate coating of any other metal, the silver being deposited direct on the iron or steel. The surface of the iron is purified by nascent hydrogen, the hydrogen being produced by the electrolysis of hydrate of potash or soda; the inventor prefers hydrate of soda. With care, inventor prefers hydrate of soda. no other salt need be added to this solution, but in manufacture such care can hardly be expected; therefore, it is expedient to add a small quantity of one of the compound cyanides: those preferred are the nickelo or The necessity cobalti-cyanides of potass. for these salts is this :- If care be not taken to regulate the current of electricity according to the strength of the solution and the number of articles in it, as well as the heat of the solution, sodium will be deposited on the articles as well as hydrogen, and if transferred to the silver solution with that on, the silver will not adhere. The compound cyanide

prevents that. When the article is coated with silver it is subjected to a heat of between 400deg. and injuring the coating. Knife blades and all cutting instruments are silvered at a pale straw temper, so that the burning in or fixing of the silver may bring them down just to a proper cutting temper. We understand that proper cutting temper. We understand that the inventor has been fitting up a manufactory for the production of silvered articles in iron and steel, and it is expected it will be brought into full operation in this present month. Beyond these, nothing further of note has been done in electro-metallurgy; and though the advance during the last twelve months has not been very striking, still gradual progress has been made.

#### PHOTOGRAPHY.

During the past year the progress of photography as a science has been small in the extreme, and commercially there has been a decline, in consequence of the depression resulting from one of those great financial panics which, for reasons known to political economists, are much more common in Great Britain than in any other country. The great total eclipse of the sun, visible last August in equatorial Asia, has called special attention to astronomical photography, and this branch of the science will doubtless be considerably improved before it is brought to bear next August upon another total eclipse, visible throughout a large portion of the United States. The recent photographic operations of the English expedition to India proved a failure, because of the want of a skilled photographer upon the staff. The plates were spoilt, because of the drying of the silver ware their surfaces and they were solution upon their surfaces, and they were all under-exposed. The first of these mishaps may always be avoided, and the German expedition at Aden avoided the latter by trying some experimental plates shortly before the totality, to get some clue beforehand to the decline in the actinism of the light produced by the cclipse. Next year, more pictures may be obtained in the same space of time, by adopting the plan of the Germans at Aden, of taking two pictures of the eclipse upon one glass plate. This is done by a simple plan well known to photographers. The sliding dark back, carrying the plate, is lengthened, so that after one picture is taken, and the light cut off, the slide is moved onwards two or three inches, and another picture taken upon the same film. This plan saves half a minute, or more, which otherwise would be lost in changing the slides.

The English apparatus worked capitally during the cclipse, but even in this the German expedition had one slight improvement. The photographic part of their apparatus was not directly fixed to the tube of the telescope lest the necessary motions of the slides should set up vibrations, so the connection was made by means of an india-rubber tube, which also excluded all stray light. In ordinary photographic operations, if the operator desires to get the maximum number of negatives in the shortest space of time, he not only furnishes his camera with a long sliding back, but he increases the number of his lenses, to throw several similar pictures upon different parts of the same sensitive plate. This raises the question whether in photographing solar eclipses it may not be possible to mount two or three reflectors or refractors at the end of a single telescopic tube, so that, say, three pictures are thrown at once upon the plate in a vertical line one above the other. Then, by shifting the plate as already described, six pictures would be obtained upon one film; or, by a second motion of the plate, even as many as nine might be impressed.

Many plans for increasing the permanency of photographic prints have been under consideration at the various societies during the past year, but the results, as regards pictures upon albumenized paper, have been small.

phite of soda solution, and thorough washing of the prints after fixing, being the best guarantees of permanency. After the washing and mounting of such pictures, rolling After the washand waxing seems to increase the stability, by the production of a print with a hard glazed surface, somewhat protected by the wax from deleterious impurities in the air. But no care in silver printing upon albumenized paper seems to give security against fading in the long run, and no photographic chemist of eminence would risk his reputation by the assertion that any such silver pictures are as durable as engravings in printing ink. Messrs. Disderi, Johnson, and others, have been producing some very delicate and beautiful prints upon wet collodion, which prints were afterwards transferred to paper. Little or nothing is as yet practically known about the durability of these pictures, but theoretically there are reasons for supposing that they will last longer than the common kind. At all events, they are more pleasing and engraving-like in appearance, and can be turned out at the same price as their better known rivals.

Carbon was the basis of the best and most imperishable of the inks in use by the monks of old, and there is no doubt that the most permanent photographic pictures at present obtainable upon paper are those produced by the carbon process. Mr. Joseph Swan first produced these pictures upon a commercial scale, and after working the process up to a great state of perfection, he recently sold his patent for a high sum to a London company, who print the pictures at Newcastle, and have offices at the west end. There is no doubt that if the general public had facilities for obtaining permanent likenesses at a moderate extra charge, many would gladly avail themselves of the opportunity, but at present no such facilities are placed in their way. There is scarcely a photographer in London who will undertake to supply carbon portraits on any terms whatever, though we believe that an establishment to turn out these pictures will soon be at work at Wil-

This question of durability of photographs is of far more national interest than is apparent at first sight. If photography had been known in the days of Queen Elizabeth, and the photographers of that time took nothing but fading pictures, so that the London life of the period was thereby pictorially lost to us for ever, except in the imperfect woodcut and flattered oil portrait, what censure we should now heap upon the photographers of old. Yet the photographers of to-day stand a good chance of falling into similar disrepute in the opinion of posterity. Month by month London is changing its physical features with great rapidity. Railways are cutting up its streets in all directions, the Holborn-hill of the past is now, practically speaking, no more, for the viaduct and new streets have already quite changed the appearance of the locality. emple Bar must, unfortunately, soon go down, as it has grown to be so great a hindrance to street traffic; and an overground railway is likely soon to entirely change the aspect of the City-road. Little is thought of these changes at the time they are made, but after the lapse of a few years, accurate pictures of London as it used to be, begin to grow in public interest. There was a time when Oxford-street ran through fields and gardens, when the first sign of civilization greeting the eye of the stranger as he entered London was the gallows, and when people were roasted alive at Smithfield for adhesion to their religious convictions. How photographs of the scenes of those bad old times would be valued at the present day, and who can tell whether the London as it is to-day may not be viewed with horror by those who The very few photographers who are really scientific men, turn out silver prints which in comparison with the general run of such pictures, are stable, fresh and good hyposul-

great historical value. It has many times been stated in these columns that about the best and certainly the most beautiful kind of permanent photographic pictures are transparencies upon collodion, cemented between two sheets of glass with Canada balsam. The balsam in its natural state will not do, as the essential oil it contains gradually evaporates, and at last the picture ceases at places to remain in optical contact with the glass. This essential oil should first be driven off by heat to such an extent that the balsam hardens as it cools, and this hardened balsam should be used in cementation processes. Even this, in some cases, tends to become brittle with age, whereby the plates have a liability to split asunder too easily, so that experiments are desirable to ascertain the best substance to mix with the balsam to increase its tough-

One reason why little progress is made in photography is that the metropolitan photographers, instead of agreeing among them-selves, have split up into three different societies, each having very little funds in hand. The oldest society was once better off, but paid away all its spare funds to a non-resident secretary. The result of all this is, that there are no funds available to push on photographic research, which is left entirely to a few private individuals, most of whom have little time to devote to investigation. If the three London societies would agree to unite into one, so as to have but one array of expenses instead of three, they could soon get a balance in hand applicable to scientific purposes.

#### CHEMISTRY.

THE year which has just closed, although marked by substantial advances in chemical science, has brought to our columns no record of any discovery of unusual or surpassing interest. But the lives of scientific labourers, as the lives of all men, "are made up of little pains and little pleasures—the great wonder-flowers bloom but once in a life-time"; and the little discoveries and little pleasures make up the great sum of happiness and pro gress. We write here mainly of chemistry in its technical relations; but when dealing with this science it is impossible to abstain from mentioning the efforts which have been made in the past year to obtain a more intimate knowledge of the constitution of the heavenly bodies, and our sun in particular, in consequence of the opportunity afforded by the eclipse. The observers have been numerous, the theorists still more numerous, but it would be wrong not to mention as among the most prominent our countrymen Huggins, Miller, Lockyer, and a younger Herschel, and among near or more distant neighbours, Jannsen, Chacornac, and Father Secchi. Their deductions and speculations have to stand the test of time and future discoveries, but they seem to show that we must regard our great lumi-nary as a mass of vividly incandescent matter, of somewhat the same composition as the crust of the planet we exist upon, but enveloped in an atmosphere of hydrogen. But the light as well as the heat are of vast importance to us, and probably we yet know but little of the wonderful influence the former exerts in the material world. We know of many wonderful changes effected by light, but Dr. Tyndall has just opened the way to the discovery of still more. We have to wait, however, for the revelation of the discoveries already made.

Some very important additions to our knowledge of the physical properties of gases have been made in the past year by Graham, Cailletet, and others. The absorption and con-densation of some by metals, the passage of many through iron at all temperatures, have formed the subjects of valuable investigations, the results of which have appeared in our

more striking discovery of giving increased force to the explosion of the cotton. As we recently announced, the explosion of a small detonating charge within a charge of com-pressed cotton literally shatters the cotton to atoms, and so developes a tremendously de-structive force. In the peaceful operations of mining and quarrying this new discovery will give increased value to gun cotton, while for torpedoes and other machines for destroying life in the gross, gun cotton becomes invaluable. We humanely give up the use of an explosive missile for destroying one life at a time, and perfect our means of hurrying hundreds out of the world in one moment. "Thus," as a French cotemporary remarked on the subject, the other day, "the devil loses

In analytical chemistry, we have recorded a noteworthy improvement in the mode of dealing with refractory minerals. By the use of the fluoride of sodium and bisulphate of potash these are fused with the utmost ease, and thus their analysis is made a matter of small difficulty. In the technical applications of our science, numerous improvements of much value have been made. Our patent list, no less than our notices, show how active our chemists and manufacturers have been in the pursuit of means of improving what we may call our staple metallic production—iron.

Much still remains to be done with this metal, but we have assurance that nothing will be left untried to perfect its manufacture. In the ornamental applications of chemistry we have recorded Liebig's improvements in his process of silvering glass, which now leaves nothing to be desired, but careful hands, in carrying out his directions. We have also recorded a modification of this process for gilding glass. Wagner also has given to us some important information on the production of bronze powders, a branch of manufacture which has been infew hands, and about which but little has been generally known.

New "soda processes" have, of course, been annunced, but as yet not one that is likely to take the place of Leblanc's. Soda waste has also been the subject of many modes of treatment, but it still offers an important field of experiment to chemists. "Waste" is a word which it is one province of chemistry to banish from our vocabulary. Our retrospect this year is necessarily short: let us go on in the hope that the year now opening may bring us more materials for next year's sur-

vey.

The obituary of the past year is happily short also. In the elder Herapath, a keen sagacious mind, of much experience in toxicology and the technical applications of chemistry has been lost; and in the younger Herapath, a man of great ability and once of much promise, was removed before he attained middle age. His name will last in scientific records in connection with his artificial tourmalines. Dr. Daubeny, with some repute as a chemist, was better known as a geologist, who will long be remembered in connection with his persevering labours on volcanoes.

#### CONCLUSION.

We have now reviewed the leading features of the past year, have pointed out the direction in which scientific improvements may be looked for, and have indicated the fields open to engineering enterprise. There is good earnest work in the future for all to perform, and there are still those among us who can perform it. Some have passed away from the scenes of their labour and toil who could apparently be but ill spared; others, however, will arise to fill their places, as and when they are required, neither sooner nor later. And so the balance in this, as in all other things, is fairly and evenly maintained. Let not him that works honestly and honorably on in life's by paths be discouraged because others have men to fame, whilst his merits are unacknow-ledged. There is room enough for all, and colleges." London: Thomas Murby, 32, Bouverie-street, E.C. bye paths be discouraged because others have

which he is entitled. If honour and renown be our due, it will overtake us at the proper season; all our fretful struggling and striving cannot hasten it—all the barricades with which envy may surround us cannot retard it. Till it comes let each and all manfully press onward to the appointed end, patiently learning the great lesson of life-endurance. In a word, let us-

Learn to labour and to wait.

#### NOTICES OF BOOKS.

ONE of the most prominent features of modern times has been distributed by modern times has been that every thing We are not content with simply possessing the information, but we must apply it. In the preface to the treatise on plane geometry, by Mr. Wormell, now before us,\* the author draws attention to the fact that the ancient philosophers were satisfied with the acquisition of abstruse knowledge, and cared little or nothing about applying it to any useful purpose; on the contrary, they regarded it as infinitely beneath them to endeavour to practically utilize their acquaintance with mathematical and physical science. Our author, however, departs in some measure—and we consider very advantageously for his readers—from the beaten track, and defines, or, rather, illustrates, many of the ordinary geometrical principles by familiar and interesting practical allusions. Instead of confining himself strictly to the elucidation of the various axioms and problems by the aid solely of lines and angles, he partially explains them by means of reference to objects of every-day occurrence. We will select one example, which will serve to demonstrate the gist of our remarks. The ordinary definition of a straight line is "that which lies evenly between its extreme points." Among other definitions given, Mr. Wormell says:—Take a piece of paper, and fold it: the crease is a straight line. There is no doubt but that to the majority of intellects, the latter definition will be the more readily comprehensible, and in addition we fail ourselves to perceive any merit in a person going in a round-about and tedious manner to gain information, when the path lies clear and open before him.

After investigating the properties of lines and angles, the third chapter introduces us to those of the circle, wherein the division of it is illustrated by allusion to the quadrant and protractor. The importance of the parallelogram in mechanics is rendered evident, and, as an instance, it is mentioned the use made of it, in the early days of machinery, by Watt, who employed it as a means of producing oscillation in the balance beam from the vertical motion of the piston. In a similar manner, the rhombus is the figure adopted to convert a vertical motion into a lateral one, as evidenced by the governor of a steam engine. The subjects of areas, polygons, and ratios are fully entered into and explained. With the accompaniment of a drawing board, T-square, and case of instru-ments, the student who chooses to apply himself, could not fail to master the whole art of geometry by means of Mr. Wormell's excel-

lent little work.

Mr. Stanley, the mathematical instrument maker, of Great Turnstile, Holborn, has just published a second edition of his very useful treatise on drawing instruments. The matter is the same as that of the first edition, with the exception of some additional matter and illustrations. These consist of the engraver's tray, the copying table, the set square for section lines, a full description of the planimeter, a gauge for cutting off drawings, and some few smaller matters. We cannot do better than recommend Mr. Stanley's work to the notice of those who may have young

friends in the engineering or architectural professions. To these latter the treatise will ust now form a seasonable and useful little present.

A few more annuals have reached us, the most prominent being Letts's diaries for the These are to be had in every new year. form and shape, and in cost from a few pence to pounds, so that every one may be suited. The No. 8 Diary published by Messrs. Letts is, perhaps, the most generally useful, and is a reasonable price. Besides the diaries of this firm, we have to notice their portable secre-taire, which will prove a very valuable invention in the office, board room, library, and even in the school room. In an exceedingly small place it contains note and letter paper of various sizes, with suitable envelopes, ink, cutlery, &c.; a small library of such books as are commonly referred to, and a receptacle for answered and unanswered letters. flap falls down in front, and whilst exposing the whole to view, forms itself the writing

We have received the "Temperance Yearbook of Facts and History for 1869," published by Mr. Tweedie, of No. 337, Strand, and "Young England's Almanack and Naturalists' Calendar for 1869," from the same office. Both these productions are full of interest to those to whom they address them-

"The Post Magazine Almanack and Insurance Directory for 1869" (W. J. Stokes, Wine Office-court, Flect-street), contains, as usual, a vast amount of useful information. It reflects great credit on its respected editor, Mr. J. Hooper Hartnoll, who has taken every care to render the work perfect for all purposes of reference. As an instance of the trouble taken by Mr. Hartnoll to secure accuracy, we may refer to the details under the head of "India Office." The whole of the departments have been remodelled, there being now eight instead of six, as heretofore; and these changes are all noticed. Every name in the list of directors of insurance companies and in the insurance directory, nearly 4,000 in number, has been verified; and no pains have been spared to secure accuracy in the whole of the information given respecting these important institutions.

#### THE INSTRUCTIONS OF THE GAS REFEREES.

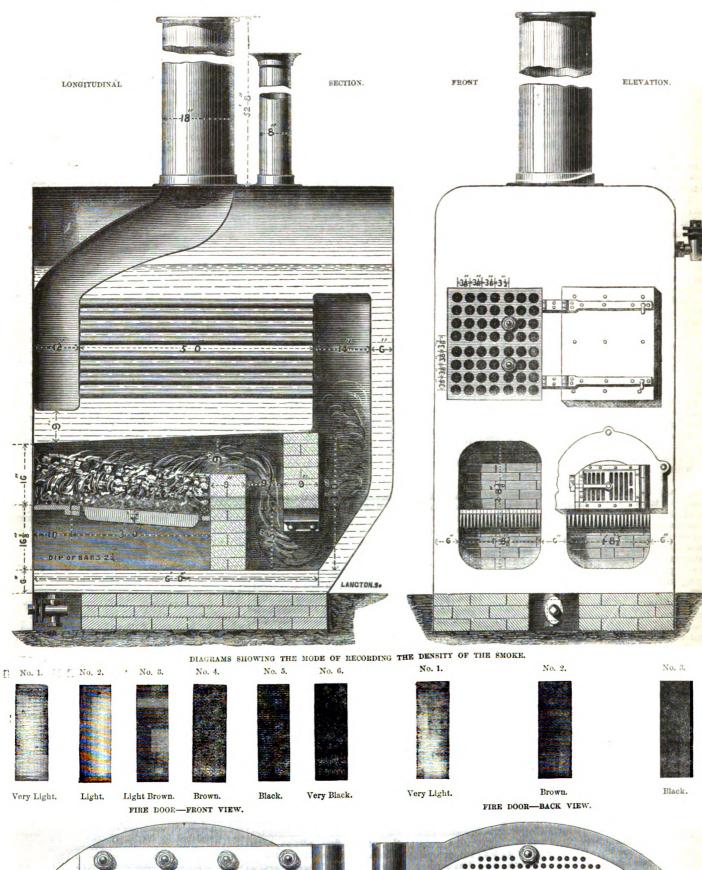

WE find we owe somewhat of an amende to the gas referees. We learn that the copy of instructions which fell into our hands, and which we had good reasons for supposing had been regularly issued, was really considered a rough proof open to correction. And, indeed, some of the directions we commented upon might well have been considered as oversights or slips of the pen. These have been corrected in the copy now definitely issued; and some instructions still retained we have little doubt will be amended as experience is gained in carrying them out. It is but fair to say that the task the referees have had has not been an easy one; and we hope that the working of the Act will show that the interests of the consumers have been well considered.

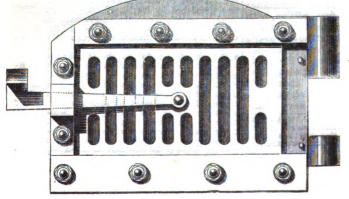

THE MANUFACTURE OF WATCHES AND CLOCKS.

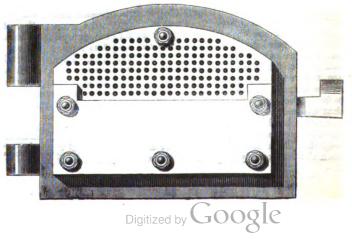

—A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, who holds the appointment to the Prince of Wales, sends this pamphlet to any address on receipt of two postage stamps, and we cannot too strongly recommend it to the notice of the intending purchaser.—| ADVT.]

### THE WIGAN COAL TRIALS, FURNACES, ETC.

#### THE WIGAN COAL TRIALS.

N August last we gave some particulars of the experiments with coal which have been carried out at Wigan, and we now append the detail report of Mr. Lavington E. Fletcher, the engineer of the Manchester Boiler Association, together with engravings illustrative of the whole subject.

REPORT.

I have now the pleasure of presenting to our members condensed tables of the results obtained at the first series of Wigan coal trials, referred to in the monthly report for July last, as well as a brief account of the mode of conducting the experiments. The special object of this series of trials was to show the suitability of the South Lancashire and Cheshire coals for use in Her Majesty's Navy. The trials were carried out at the expense of the South Lancashire and Cheshire Coal Association, under the superintendence of the late Dr. Richardson, of Newcastle, and myself, and it is with the permission of that Association that these particulars are presented to our members. I propose to describe, in the first in-stance, the mode of conducting the investigation with the testing apparatus employed; in the second, the preliminary trials, with the modifications in the furnaces and treatment of fires arrived at; and in the third, the permanent trials, with their results.

1. Description of the Mode of Conducting the Trials and of the Testing Apparatus EMPLOYED.

The principle on which these trials were conducted was simply that of ascertaining by practical experiment in a steam boiler how much water a pound of coal would evaporate; also at what speed that could be done, and whether with or without the formation of smoke. To this end all the water evaporated was accurately measured; the coal carefully weighed; and the time expended in doing a given amount of work noted; added to which the amount of smoke emitted was

Measurement of the Water.—Water meters are not always to be relied upon, and, therefore, to avoid every chance of mistake, or even suspicion of inaccuracy, a tank was employed of sufficient size to carry through an entire experiment with a single charge. This tank, which had a superficial area of 50 square feet, and thus a capacity of 2641b. per each inch in depth, was fitted with a float, which, reposing on the surface of the water, rose and fell with it, and operating upon a pointer travelling over a scale graduated in feet and inches, indicated the precise amount consumed, as well as the rate of progress throughout the trial.

It is usual in such trials to evaporate the water at atmospheric pressure, so as to afford a common for the comparison of different experiments, while it has the further advantage of dispensing with the necessity of a pump, and of very much reducing the chances of waste from leakage. The plan had been adopted by the Admiralty in previous trials, and, therefore, was followed on the present occasion. The tank was placed at a short present occasion. The tank was placed at a short distance from the boiler, and at a sufficient height for the water to flow into it by its own weight, the two being connected by a pipe 2in. in diameter, which was fitted with a stop tap, so that the supply could readily be controlled by hand, while the whole was placed so as to be quite open to view, so that no loss from leakage could go on unobserved.

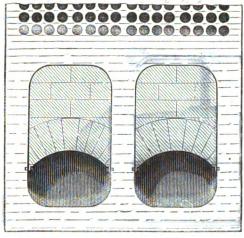

The feed-water was supplied to the boiler at its natural temperature, whatever that might happen to be, but as this varies at different times, and clearly affects the result, it is important that an allowance should be made for these variations, so as to admit of the correct comparison of different experiments. It is, therefore, customary to qualify the amount of water evaporated by the temperature of the feed, and to reduce it to a standard of so many pounds of water evaporated from a temperature of 212deg. or 100deg. as may be decided on. As the standard of 100deg. had been adopted by the Admiralty in previous experiments, it was adhered to on the present occa-

sion, and the necessary qualification made.

Mode of Weighing the Coal.—The coal was weighed in charges of 200lb., and shot down in front of the boiler so as to be kept entirely distinct from the general stock.

Description of the Test Boiler.

SECTION SHOWING INVERTED BRIDGE.

yard, Keyham, for testing the value of coals, it was proposed by Dr. Richardson that to avoid all question a precisely similar one should be used for the Wigan trials, and with this view a fac-simile of the Keyham test boiler was made from drawings kindly furnished by T. W. Miller, Esq., chief en-gineer at Her Majesty's Dockyard, Keyham. This boiler was of very cramped proportions, and by no means calculated to develope the highest results from the coals, but it was adhered to for the reasons just given. It measured 7ft. Sin. in length, 8ft. 10in. in height, and 5ft. in width, and contained 124 flue tubes, 5ft. long and 2¼in. diameter inside, with two furnaces each 1ft. 8§in. in width. The heating surface afforded by the tubes was 365 square feet, by the flame chamber and furnaces, including the ashpit, 128 square feet, making a total of 493 square feet of heating surface. The equipment of square feet of heating surface. The equipment of the furnaces was of the usual class, consisting of an ordinary firedoor, dead-plate, set of firebars, and single vertical brick firebridge, the firedoor being fitted with a sliding grid for the admission of air when required, and a perforated box at the back for the dispersion of the current. To give a better idea of the proportions of the boiler with the furnace mountings two cuts are appended, the first of which gives a longitudinal section through one of the furnaces, the other a front external elevation, added to which there is subsequently given an enlargement of the firedoor.

Method of Estimating the Amount of Smoke.-To accomplish this, an observer watched the chimney throughout the whole experiments, and noted every minute in which smoke occurred, the density being defined by gradations of 1 2 3 4 5 6, as shown in the diagram.

In the tables accompanying this report, however, the six gradations just given are reduced to three for the sake of simplicity, under the designations of "very light," "brown," and "black," as shown in the diagram.

2. PRELIMINARY TRIALS WITH THE MODIFICATIONS MADE IN THE FURNACES AND TREATMENT OF THE FIRES.

At the commencement of the trials only 8.01lb. of water were evaporated by 1lb. of coal, and 35.88 cubic feet of water by the boiler per hour, with a consumption of 20lb. of coals per hour per square foot of firegrate; subsequently, however, the results were considerably improved, and 11 11lb. of water were evaporated by one of coal, with a speed of 46:19 cutic feet of water per hour, and 25lb. of coal per hour per square foot of firegrate. This improvement was obtained simply by slight modifications in the proportions of the furnaces and treatment of the fires.

It would be interesting to trace all these modifications, and to give the results of each. This, however, would be a work of too great length for the present occasion. Suffice it, therefore, to say, that 115 preliminary experiments were made, during which it was found of advantage to reduce the length of the firegrate from 4ft. to 3ft., to adopt a blind dead plate in preference to a perforated one, and to slightly lower the level of the firegrate so as to increase the flame chamber above the bars, while there is no doubt that a further advantage would have been gained by lowering the bars still baseription of the less Boner.—As these trials would have been gained by lowering the bars still more had special reference to the suitability of the coals of this district for steam purposes on board Her Majesty's Navy, a boiler of the marine multi-tubular type was adopted; and, further, as a special one is employed at Her Majesty's Dock-while the addition of an inverted or hanging bridge

behind the ordinary vertical one was found of advantage in preventing smoke, its action being to assist in mixing the gases and maintaining the temperature of the furnaces. The construction of temperature of the furnaces. The construction of this bridge will be readily understood on reference to the accompanying cut.

The following figures will show the result of its working :-

COMPARATIVE TABLE OF RESULTS WITH AND WITHOUT INVERTED BRIDGE.

	of	at	Smoke per hour			
NAME OF COAL AND CHARACTER OF TRIAL.	Lbs. of Water at 10 evaporated per lb. Coal.	Cubic feet of Water 100° evaporated' I hour.	Minutes of Very	Minutes of Brown.	Minutes of Black.	
Haigh Yard Coal with Inverted Bridge	11.24	47:38	0.5	0	0	
without Inverted Bridge	11.05	51.31	2.5	0	0	

The number of perforations for the admission of air through the firedoors were also modified. the first instance, there were 730 giving an area of 3.2 square inches per square foot of firegrate. These were afterwards reduced by bolting a blank plate over the lower part of the doors, so as to make the number of perforations 342, equal to an area of 1.6 square inch per square foot of firegrate. It is thought that the benefit from this change arose more particularly from the alteration in the point admission, and it was afterwards found necessary with the thickest fires to leave the doors lin. or  $1\frac{1}{2}$  in. ajar for a minute or so after firing to prevent the formation of smoke. The proportions of the the formation of smoke. The proportions of the furnaces finally adopted, with the length and level of grate, and arrangement of fire bridges, are those shown in the cuts of the boiler already referred to, while the enlarged view of the firedoor will show its general construction and the final number of perforations:

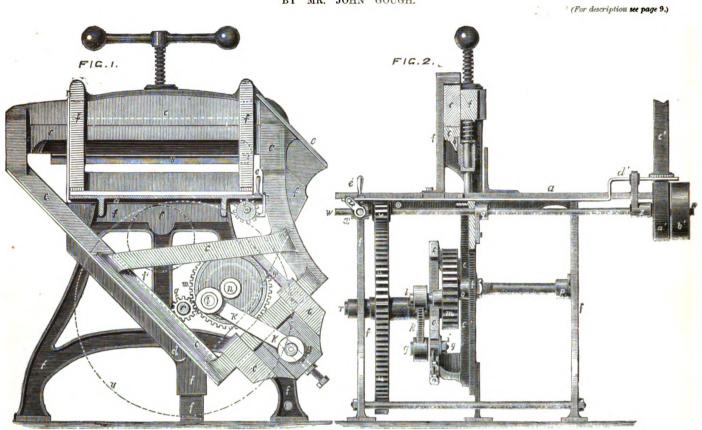

In addition to the modifications in the proportions one termed "spreading," the other "coking." In "spreading" firing, the coal is scattered evenly over the whole surface of the firegrate, commencing generally at the firebridge and working forward to the firedoor. In "coking" firing, the charge of coal is thrown on to the dead plate in front of the bars and allowed to lodge there for a time in order that the mass may become coked through, and when that is done, the crest is pushed back towards the bridge, and another charge thrown on to the front of the fire in its place. In this way the gases are gradually evolved from the coal at the front, while a bright fire is maintained at the back, over which the gases pass. On trying the two plans, coking firing was found to give a more economical result than spreading, and at the same time to produce less smoke, while, in addition, a higher result was obtained by thickening the fire from 6 to 9in., and again from 9 to 12in. "Coking" firing was therefore adopted as the standard firing was therefore adopted as the standard method, and with fires 12in. thick, while the fur-naces were charged alternately, and the perforations allowed to remain open for a few minutes after charging for the prevention of smoke.

#### PASSENGER LOCOMOTIVE ENGINE.

OUR double page engraving this week represents a fine passenger locomotive engine, constructed by Messrs. Kitson and Co., of Leeds. The design of this engine leaves little to be desired, and in of this engine leaves little to be desired, and in point of finish the workmanship fully maintains of cylinders, 1ft. 4in.; stroke of cylinders, 1ft. 10in.; the high character long enjoyed by the firm. The following are the principal dimensions:—Diameter distance between centres of cylinders, 2ft. 5in.; diameter of coupled wheels, 5ft. 6in.; diameter of leading wheels, 4ft.; total wheel base, 15ft. 6in.; centres of coupled wheels, 7ft. 9in.; length of barrel of boiler, 10ft. 6in.; diameter of barrel of boiler outside, 3ft. 10in.; height of centre line of boiler above rail, 6ft. 14in.; length of firebox casing, 4ft. 9in.; height of ditto at front, 6ft. 6\frac{3}{2}in.; height of ditto at foot, 4ft.; length of firepox at a bottom, 4ft.; length of firepox at front, of ditto, 3ft. 5in.; height of firebox at front, width of ditto, 3ft. 5in.; height of firebox at front, casing at bottom, 4ft.; length of firegrate, 4ft. 2in.; width of ditto, 3ft. 5in.; height of firebox at front, 4ft. 103in.; height of ditto at back, 4ft. 13in.; length of tubes between tube plates, 10ft. 93in.; diameter of ditto outside, 2in.; number of tubes, 140. Heating surface: tubes (external surface), 790 square feet; firebox, 82 square feet; total, 872 square feet, 16th. cases of firebox, 82 square feet, 16th. cases feet. 790 square feet; firebox, 82 square feet; total, 872 square feet; area of firegrate, 14½ square feet; steam space with water level 4in. above firebox crown, 36 cubic feet; weight of engine empty—on leading wheels, 8½ tons; ditto on driving wheels, 8½ tons; ditto on trailing wheels, 8½ tons; total 25½ tons; weight of engine in working order—on leading wheels, 9 tons; ditto on driving wheels, 9½ tons; ditto on trailing wheels, 9½ tons; total, 28 tons.

#### GEARING FOR PAPER-OUTTING MACHINES.

THE invention which we illustrate on page 8, has been patented by Mr. John Gough, of 42, Kirby-street, Hatton-garden. It consists of improved gearing for actuating the knife in paper-cutting machines, and is specially applicable to Wilson's machines, in which the first motion shaft requires to be reversed in order to bring back the knife. In this class of paper-cutting machines the diagonal frame to which the knife is attached is now actuated by a pinion fast on the second motion shaft of the machine; this pinion is caused to gear with

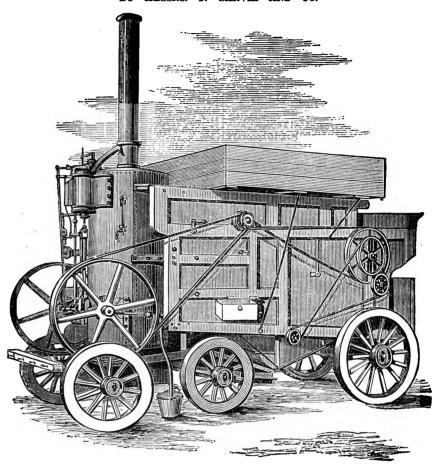

requires to be reversed in order to bring back the knife. In this class of paper-cutting machines the diagonal frame to which the knife is attached is now actuated by a pinion fast on the second motion shaft of the machine; this pinion is caused to gear with two toothed racks fixed opposite to one another on the interior of the lower portion of the diagonal frame. Into one rack it gears directly, and into the other through the medium of a toothed wheel mounted on a stud fixed in the frame of the machine. Mr. Gough disponses with these toothed racks and gives the required motion to the frame by means of a crank on the stud, the pin of which crank is fixed in the side of the toothed wheel on the stud. The motion of the crank is transmitted to the diagonal frame through the medium of a connecting rod.

Fig. 1 in our engraving represents a front elevation of the machine, partly in section; fig. 2 represents a side elevation of the machine; also partly in section. a represents the table for giving support to the paper while being cut; b, the knife; and c, the diagonal frame to which it is attached, and which frame is free to move up or down in the guides a and a, formed in the framework / of the machine; g represents a pin fixed in the lower portion of the diagonal frame c, which pin can be adjusted as to position by means of the screw h, and made secure by means of the nut i; k denotes a rod by means of which the pin g is connected with the crank pin i, which is shown fixed in the side of the toothed wheel m, which wheel is mounted on the stud n, which is supported at and p in the frame / of the machine; g represents a pinion which gears into the toothed wheel m, and which is fixed on the second motion shaft r, which is carried in the bearings s and in the frame / of the machine. Next the bearing s a large toothed wheel w is fixed, which gears into a pinion v, fixed on the first motion shaft w; formed in the frame / of the machine.

The mode of operation is as follows:—The paper having been placed on the table a, a

#### ENGINE AND COMBINED THRASHING MACHINE.

BY MESSRS. T. GARVIE AND CO.

that the action of the machine becomes continuous, and the first motion shaft does not require to be reversed, as at present is the case in this class of

#### PORTABLE ENGINE.

A BOUT two months since, we described and illustrated a very good horizontal engine, by Mr. T. Wilkins, of Ipswich. We now give an example of one of another class by the same maker. It is a portable engine which can compete with most of its kind for cheapness. A cast-iron bed-plate is belted on to a pair of T-iron horizontal stays connecting the belier with the fore axle, which is mounted on a large spherical joint to allow for inequalities on the road, as is done in the case for inequalities on the road, as is done in the case of some French portable engines. The engine is 4-horse power. The boiler is 5ft. 6in. by 3ft., fire-box 2ft. 6in. by 3ft. high, and has eight 2\frac{1}{2}in. tubes from its roof to top of boiler; the wheels are 4ft. and 2ft. 9in. diameter, and fly-wheel 3ft. 6in.; the cylinder is 6\frac{1}{4}in., stroke 10in., pressure carried 45ib., total weight of engine short 45ext. total weight of engine about 45cwt. The crank shaft bearings are solid block brass bushed. Simplicity is certainly carried to the fullest extent in this engine, and its cheapness will recommend it to

#### COMBINED ENGINE AND THRASHING MACHINE.

WE illustrate in the annexed engraving a new combined engine and thrashing machine, invented and built by Messrs. T. Garvie and Oo., of Fish-street, Aberdeen. The front frame on which the engine stands is made of oak, and two rings of angle iron, one riveted to boiler and the other fastened to the frame, forms a swivel. Besides this, the two front wheels swivel with a ball and socket joint to a certain extent. The reason for putting the boiler at this end is because the engine frame draws the machine, which is light, and consequently there is no undue strain on the mill-framing. The drum-shaft, as will be seen, is driven by two belts from the two fly-wheels. The boiler is of the tubular construction,

with a cone plate over the top tube-plate, which connects to the funnel and gives a large amount of steam room. The boiler is made of Lowmoor Iron steam room. The boiler is made of Lowmoor Iron throughout, and is 7ft. 6in. by 3ft. The engine has a 6in. cylinder and 10in. stroke; fly-wheels, 3ft. 6in. diameter; speed of engine, 205 revolutions per minute; working pressure of boiler, 60lb. to 80lb. The whole weight of engine and boiler is 30cwt. Two horses draw the machine on good roads and three on bad roads. The machine is at present doing work through Aberdeenshire, and has not had any repairs.

#### INSTITUTION OF CIVIL ENGINEERS.

THE annual general meeting of the Institution of Civil Engineers took place on the 22nd ult., Mr. C. H. Gregory, president, in the chair. From the report of the Council we learn that the following papers were read and discussed during the last session:—The irrigation in India, Spain and other warm elimeters and on the Spain, and other warm climates, and on the proper construction of irrigating canals; the manufacture and wear of railway bars; the relation of the fresh water floods of rivers to the areas and physical features of their basins; on floods in the Norbudda Valley, with remarks on monsoon floods in India generally; on the Victoria Bridge on the line of the Victoria Station and Pimlico Railway; on new the Victoria Station and Pimlico Railway; on new railways at Battersea, and the widening of the Victoria Bridge; the City Terminus Extension of the Charing-cross Railway, embracing a description of the Cannon-street bridge and station; the durability of materials; the supporting power of piles, and on the pneumatic process of sinking iron columns, as practised in America; and the experimental determination of the strains on the superposity ties of a howstring girder. Although experimental determination of the strains on the suspension ties of a bowstring girder. Although the topics thus dealt with had been comparatively limited in number, yet it was believed they might be fairly regarded as representing some of the principal problems now engaging the attention of engineers. There was, for instance, probably no question of greater national importance, having regard to the interests and welfare of so many of the Queen's subjects, than that of irrigation. Hitherto the records of the Institution had been a blank upon this branch of engineering practice while treatises on the subject, at least in the English language, had previously been almost entirely

Manual Section Control Control

For these communications various premiums had been awarded, which were presented after the reading of the report, including Telford medals and Teling of the report, including Telford modals and Telford premiums of books to Messrs. G. Higgin, C. P. Sandberg, W. Wilson, C. D. Fox, and J. W. Barry, and Lieut-Col. O'Connel, R.E.; a Watt medal to Mr. E. Clark; a Telford medal to Mr. W. J. M'Alpine; Telford premiums of books to Messry. T. Login, A. Wilson, and W. Airy; and the Manby premiums of books to Mr. A. C. Howden. It was noted that Mr. E. Clark had previously received a Telford medal from the Institution.

The report further stated that the new building

The report further stated that the new building, with furniture, cost upwards of £17,000. There were on the books on November 30 last, 16 honorary members, 637 members, and 896 associates, making a total of 1,549, inclusive of students. The admissions to the class of students, which had only been in existence one session, had amounted to the same date to 133.

The deceases announced during the year had been:—Sir David Brewster and Lord Brougham, been:—Sir David Brewster and Lord Brougham, honorary members: George Rowdon Burnell, Alexander Gordon, Daniel Gallagher Grose, George Alfred Jermyn, Michael Lane, George Holsworthy Palmer, Thomas Rhodes, and William Swinburne, members; Henry Goulburn Anderson, Thomas Long Colley, Isaac Curran, Andrew Henderson, Peter Hogg, Frederic Cornell Reynolds, Robert Sharpe, Francis Adolphus Smart, Thomas Hitchin Smith, William Strode, William Swann, and John Vaughan, associates. Vaughan, associates.

The following gentlemen were elected to fill the several offices on the council for the ensuing year:—Charles Hutton Gregory, president; Joseph Cubitt, Thomas Elliot Harrison, Thomas Hawksley, and Charles Vignoles, vice-presidents; James Aberand Charles Vignoles, vice-presidents; James Abernethy, William Henry Barlow, John Frederich Bateman, Joseph William Bazalgette, Nathaniel Beardmore, Frederick Joseph Bramwell, James Brunlees, George Willoughby Hemans, John Murray, and George Robert Stophenson, members; and Major-General Sir W. T. Denison, K.C.B., and Frederick Ransome, associates,

#### NEW YORK SOCIETY OF PRACTICAL ENGINEERING.

THIS Society held its usual semi-monthly meeting at its room in the Cooper Union Building, New York City, on the evening of Tuesday, October 18, James A. Whitney, the President of the Society,

Tat its room in the Cooper Union Building, New York City, on the evening of Tuesday, October 18, James A. Whitney, the President of the Society, presiding.

"Air Motors and Atmospheric Propulsion" constituted the subject regularly before the meeting and a paper upon the same, by Perry Dickson, M.E., was read by the recording secretary, Mr. William B. Harrison. The paper set forth the peculiarities, of some of the earlier English projects in this line, which a score of years since were prominently before the public, and also weighed and compared the merits and demerits of the several plans now meeting with more or less approval at the hands of engineers. Foremost among the earliest-tried systems was that in which a tube was laid longitudinally between the tracks. with an opening formed lengthwise in its upper part for its whole length. The piston travelling within the tube was connected by an arm extending through the slot with the car above, and the slot itself was covered by a flap valve attached at one edge to one side of the slot, so as to yield and open to permit the arm to pass and yet close the slot in front of and behind the arm. The air being exhausted in front of the piston, the latter was moved along by the pressure of the atmosphere behind it, and of course propelled the car with which it was connected. In another plan the slot was closed by the two elastic lips composed of pipes of soft material filled with air, the piston arm being made flat like a knife blade, and sliding between the lips which closed before and behind it; but these, as well as several other methods which were tried, proved futile in practice, inasmuch as it was found impossible to keep the valve mechanism in proper repair. When in good order, either of these devices enabled a pressure of about 101b. per square inch on the pistons to be obtained, and very good results were thus secured.

The writer also considered the mode frequently proposed of carrying tanks on the cars to hold the air under compression for the driving engines,

case the air was compressed to a high degree, which is the only way that would enable the size of the tanks to be reduced. With regard to the plan of employing tanks removable from the car when exhausted, so as to be replaced by those charged with air compressed for use, the loss of time involved in the substitution of one tank for another at volved in the substitution of one truk for another at frequent intervals was deemed sufficient to condemn it. The author also commented upon the "pneumatic tube" plan, in which the carriage is itself the piston, and is propelled through the tubular way by exhausting the air in front thereof. His opinion did not differ materially from that very generally held, that although this system is capable of useful development in the carriage of parcels, it cannot compete successfully with other means of passenger transportation. Carbonic acid gas engines, the use of which for car propulsion has been sometimes suggested, were dismissed with a few remarks, the gist of which was, that if the gas was wasted it would prove too extravagantly expensive for practical purposes, while if it was collected in a receiver upon the car after leaving the engine, such receiver would be of ridiculously large dimensions. The writer concluded by explaining a plan of his own, which he claimed to be free from the systems hitherto propounded. In this a tubular magazine of compressed air is to be laid between the tracks, and furnished with devices by which the air is automatically conveyed at intervals from the magazine to small-sized tanks on the car, this being done when required without stopping the car, and the air being compressed in the magazine by the aid of stationary engines.

A lively discussion succeeded the paper, in the frequent intervals was deemed sufficient to condemn

pressed in the magazine by the aid of stationary engines.

A lively discussion succeeded the paper, in the course of which Mr. Creuzbauer stated that he thought Mr. Dickson's method possessed one important advantage—in this, that the air could be used at a comparatively low pressure. When the air is compressed, say, by a pressure equal to seven atmospheres, the radiation or loss of the resultant heat will reduce the working value or power of the same to about four atmospheres, and this ratio of loss increases in the same proportion as the pressure is increased.

S. Carson explained a system brought forward by himself some years ago, in which the car tanks were replenished at intervals from stationary reser-

by filmsen some years ago, in which the car tains were replenished at intervals from stationary reservoirs, and the valves of the car engine were so arranged as to secure a uniform speed, by admitting the air to the engine in inverse proportion to the degree of pressure in the tank.

Mr. J. K. Fisher said that while he possessed but little faith in atmospheric propulsion, he believed no difficulty would be experienced in retaining air in the tanks at a high pressure. In some of the carly English trials the tanks were commonly charged on Saturday, and left over in that condition until the succeeding week.

Mr. James Harrison showed a model of a machine for cleaning the snow from streets, railway tracks, &c., by melting it, and which differed from an apparatus exhibited by him at a previous meeting of the Society, chiefly in the use of a furnace, in connection with exhaust steam from the boiler, to melt the snow as fast as carried to the top plate of the machine as it moves along. The consideration of this invention drew out several ideas relating to the melting of the snow as it lies on the pavement, the melting of the snow as it lies on the pavement, the use for the purpose of downward blasts of hot air, of exhaust, and of combined waste steam and hot products of combustion from the boiler furnaces, being severally indicated by different members.

MANUFACTURE OF EXTRACT OF MEAT.

MANUFACTURE OF EXTRACT OF MEAT.

THE following particulars of the manufacture of Liebig's extract of meat at the company's establishment at Fray Bentos, Uruguay, South America, are from the Buenos Ayres "Standard":— The new factory is a building that covers about 20,000 square feet, and is roofed in iron and glass. We first enter a large flagged hall, kept dark, cool, and extremely clean, where the meat is weighed and passed through apertures to the meat-cutting machines. We come to the beef-cutting hall, where are four powerful meat-cutters, specially designed by the company's general manager, Mr. Gribert; each machine can cut the meat of 200 bullceks per hour. The meat, being cut, is passed to "digerators" made of wrough tiron; each one holds about 12,00016 of beef; there are nine of these digerators, and three more have yet to be put up. Here the meat is digerated by high-pressure steam of 751b. per square inch; from this the liquid which contains the extract and the fat of the meat proceeds in tubes to a range of fat separators, of peculiar construction. Here the fat is separated in the hot state from the extract, as no time can be lost for cooling operations, otherwise the fat is separated in the hot state from the extract, as no time can be lost for cooling operations, otherwise decomposition would set in in a very short time. We proceed downstairs to an immense hall, 60ft. high, where the fat separators are working; below them is a range of five cast-iron clarifiers, 1,000 gallons each, worked by high-pressure steam through Hallet's tube system. Each clarifier is provided with a very ingenious steam tap; in the monstrous clarifiers the albumen and fibrine and phosphate of magnesia

are separated. From hence the liquid extract is raised by means of air-pumps, driven by two 30-horse power engines, up to two vessels about 20ft. above the clarifiers; from thence the liquid runs to the other large evaporators. Now we ascend the staircase reaching the hall, where two immense sets of case reaching the hall, where two immense sets of four vacuum apparatus are at work, evaporating the extract by a very low temperature; here the liquid passes several filtering processes before being evaporated in vacuum. We now ascend some steps and enter the ready making hall, separated by a wire gauze wall, and all windows, doors, &c., guarded by the same to exclude files and dust. The ventilation is maintained by patent fans, and the place is extremely clean. Here are placed five ready making pans, constructed of steel plates with a system of steel discs, revolving in the liquid extract. These five pans, by medium of discs, 100 in each pan, effect in one minute more than two millions square feet evaporating surface. Here concludes the manufacturing process. The extract is now withdrawn in large cans, and deposited for the following day. Ascending a few steps we enter the decrystallizing and packing hall, where two large cast-iron tanks are placed, provided with hot water baths under their bottoms; in these tanks the extract is thrown in quantities of 10,000lb. at once, and here is decrystheir bottoms; in these tanks the extract is thrown in quantities of 10,000lb. at once, and here is decrystallized and made a homogeneous mass, and of uniform quality. Now samples are taken and analyzed by the chemist of the establishment, Dr. Seekamp, under whose charge the chemical and technical operations are performed. It may be mentioned that the company's butcher kills at the rate of eighty oxen per hour; separating by a small double-edged knife the vertebre, the animal drops down instantaneously on a waggon and is conducted to a instantaneously on a waggon, and is conducted to a place where 150 men are occupied dressing the meat for the factory, cutting each ox into six pieces; 400 are being worked per day.

#### Correspondence.

THE HAND SCREW PROPELLER FOR BARGES AND BOATS.
TO THE EDITOR OF THE "MECHANICS" MAGAZINE.

SIR,—I shall feel obliged by your allowing the following remarks to appear in your very useful magazine, upon what I believe to be a valueble and new invention. Having frequently noticed the labour and difficulty of propelling and guiding barges and boats, I have, for some time past, devoted my attention to the construction of means whereby these things can be done with less labour and greater efficiency; and I think I have succeeded in the attempt. The mechanism is simple, easily worked, inexpensive, and soon repaired when out of order, which it is not likely to be by fair means. It consists of a screw working on an axis supported by two iron uprights at the stern of the boat, and put in motion by means of a crank, on the axis of which a grooved wheel is fastened. Round this wheel a strap or chain passes to a smaller wheel which is securely fastened to the axis on which the screw is fixed. To the second iron upright from the stern of the boat, the rudder is attached, and both it and the crank are easily worked by one person standing on SIR,-I shall feel obliged by your allowing the

To the second iron upright from the stern of the boat, the rudder is attached, and both it and the crank are easily worked by one person standing on the deck, which projects sufficiently far to protect both screw and rudder from injury. The screw may also be turned by means of cog-wheels working upon each other, the smallest being attached to the axis on which the screw is fixed. I name this the "Hand Screw Propeller;" and, by means of which, I believe the barge, which must now not only wait for the tide to carry it on its journey, but every other description of craft must move out of the way for it, may, with the tide, be made to move at the rate of from six to eight miles an hour, and be readily moved out of the way of other vessels on the same water.

The barges on canals would, I hold, be greatly benefited thereby; their rate of speed would not only be increased, but the working may be done by one man, in place of, as now, employing a man, a boy, and a horse. To fishing boats, the addition of the "Hand Screw Propeller" would be a great advantage, especially during calms. It may also be advantageously employed in propelling and guiding at the same time small boats. At present, I do not know that anything of the kind has ever been invented, nor have I ever seen any description of barge or boat propelled in the manner I now propose to propel them. If it be an invention, the credit will be mine; but, whatever good there may be in it, or advantage drived from it, is now hereby given to the public, and should it be the means of promoting commerce, and lessening the labour of our watermen, I shall be repaid. I have made a working model, and any persons engaged in barge or boat building, or interested in their navigation, can inspect it by calling on me.— I am, Sir, yours, &c.,

Brunswick House, Tanner's Hill,

New Cross, London. I am, Sir, yours, &c., Brunswick House, Tanner's Hill, New Cross, London.

REVOLVING DISC BATTERIES FOR HARBOUR AND COAST DEFENCE.

SIR,—In order to avoid alluding to the subject in my next and concluding letter on the defence of fortresses,

<sup>\*</sup> Reported in the "American Railway Times."

permit me to state that since writing my ninth letter, in the which I alluded to a floating battery called as above, I have had an opportunity of seeing, in the house of an old friend of mine, in this city, in the designs of a circular floating structure invented by Mr. Elder, of Glasgow, and I have no doubt that anyone interested in the subject will, on perusing Mr. Elder's work, arrive at the conclusion that that gentleman's circular structures will, in steadiness, flotability, and shot-and-ram resisting strength possess a very great superiority.—I am, Sir, yours, &c., G. J. GUNTHER.

Bremen, December 22.

MINING ACCIDENTS.

SIR.—Your remarks in last week's issue, on the slowness of the mercurial barometer in indicating the danger which threatens the miner from a change in the density of the air, are very just and indisinthe density of the air, are very just and indisinthe density of the air, are very just and indisputable. Permit me to say that a quicker (because putable. Permit me to say that a quicker (because more visible) warning may be had from a water more visible warning may be the work, and if it be tap, it is quickly and easily set to work, and if it be refilled occasionally, its indications may be relied upon. A glass tube 3ft. 6in. long is required at the level of the oscillations; all the rest may be of iron or other tubing.—I am, Sir, yours, &c.,

A PINE steamer, of 1,000 tons burden and 300-horse A FINE steamer, of 1,000 tons burden and 300-horse power, was launched on November 30, at Trieste, from the shipbuilding yard of S. Marco. She was named the "Wassitai Tigiard," and is the property of the Sultan of Turkey.

A DISPATCH from Berlin says that, in a series of experiments which have recently been made in that crity the Catling battery gun has proved inferior to a

city, the Gatling battery gun has proved inferior to a

Prussian gun.

In addition to the targets constructed on the plans
In addition matter and Barnard, of the Engineer In addition to the targets constructed on the plans of Generals Totten and Barnard, of the Engineer Corps, of which trial has been made at Fort Monroe, a third target has been constructed in accordance with plans submitted to the Engineer Board by General Wright. This target was tried at Fort

Delaware.

The Royal Mersey Yacht Club has presented to the National Lifeboat Institution £75, being the mount of the proceeds of a ball held in the club-house, Liverpool, in aid of the great and national objects of the Institution. The committee of the society have expressed their high appreciation of this substantial mark of sympathy and support on the part of a club so capable of knowing the great value of the lifeboat work.

The two English steamers, "Norfolk" and "Collingwood," which were caught in the ice at Cronstadt and then cut a passage out into the open sea, after all the trouble and expense, were unable to get farther than the island of Seskar, where they found the Cronstadt, where they will now remain frozen in till next May.

next May.

The report of the secretary of the American navy exhibits the operations of that department and of the navy during the year. A considerable reduction of the force has been effected. There are forty-two of the force has been effected. There are forty-two which are established in different parts of the world. Three of these vessels are returning to the United Three of these vessels are returning to the United States, and four are used as storeships, leaving the States, and four are used as storeships, leaving the States, and four are used as storeships, leaving the States, and four are used as storeships, leaving the States, and four are used as storeships, leaving the States, and four are in use, armed with 696 guns. The total number of vessels in the navy 356 guns. The total number of vessels in the navy is 206, mounting 1,743 guns. Eighty-one vessels of every description are in use, armed with 696 guns. This with regret that we learn the death of Major-IT is w

The following extraordinary illustrations of prolonged existence appeared in the obituary of the a Times" of the 23rd ult., where the deaths of six ladies are recorded whose united ages amounted to 519 years, giving an average of exactly 86 years and and 6 months to each. Their respective ages were two at 83, one at 84, one at 85, one at 91, and the oldest had reached the great age of 93. The same obituary recorded the death of a gentleman at 90 years of age, which, added to the above total, would give an average of exactly 87 years to each of these seven persons. A medical practitioner in this metropolis recently stated that he had just seen ten patients whose ages averaged 87 years and 10 months each.

### Watents for Inbentious.

#### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES-1888, 1890, 1904, 1936, 1939, 1942

UILDINGS AND BUILDING MATERIALS-1899, 1903, 1907, 1981

1981
CHEMISTRY AND PHOTOGRAPHY—1885, 1909, 1912, 1920, 1940, 1945, 1953, 1954, 1972, 1974
CULTIVATION OF THE SOIL, including agricultural implements and machines—1893, 1941, 1943, 1963, 1975, 1982
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1910, 1913, 1923, 1932, 1946, 1956, 1957, 1960, 1964, 1968, 1976, 1975, 1979
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1944, 1970
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1836, 1887
GRNERAL MACHINERY—1898, 1911, 1914, 1915, 1924, 1926,

SIME-RECEPETS, Jewellery, musical instruments, &c.—1886, 1887.

WARFARE—1894, 1931, 1950

1884 A. MUNBO. Arbroath. Forfar, and W. B. ADAMSON, Glasgow, N.B. Manufacturing tools for hewing or cutting stone. Dated June 9, 1868.

This invention, in the first place, relates to a new method of manufacturing tools to be used for the purpose of hewing or cutting stone, slate, marble, and other substances, and it consists in the manufacture of such tools in a direct manner, so that, when made by this method, they are at once fit for use. The invention relates, in the second place, to the employment of metallic compounds or alloys, as the material of which such tools are formed.—Patent

abandoned.

1885 J. H. JOHNSON, Lincoln's Inn-fields. Treatment of oxide of iron. (A communication). Dated June 9, 1888.

According to this invention, it is proposed to mix the powdered oxide of iron (obtained from the calcination of iron pyrites) with small coal, and to agglomerate the mass by the addition thereto of tar, the whole being pressed into bricks or blocks by suitable machinery, such as is employed in the manufacture of artificial fuel.—Patent abandoned.

abandoned.

1886 G. DAVIES, Serle-street, Lincoln's Inn-fields.

Lounging chairs. Dated June 10, 1868.

The patentee claims, first, the particular arrangement of the ironwork for producing the inclination of the back and other movable parts. Second, the improved mechanism for fixing the lounging chair at any desirable inclination. Third, the arrangement of the plank for supporting the feet or raising the leg cushion at will; and, fourth, the general improved arrangement of the various parts with regard to each other for increasing the case and comfort of the occupant.—Patent completed.

1887 P. Fraye, Walbrook, City. Harmoniums. (A communication). Dated June 10, 1868.
Hitherto organs or harmoniums with free valves have not proved satisfactory, either to the performer or to the auditors, the system in use up to this day giving a marked predominance to the base over the upper scale. This system obviates all difficulties hitherto met with in the construction of the above instruments.—Patent abandoned.

1898 W. FERRIE, Monkland Iron and Steel Works, Lanarkshire, N.B., Smelting or blast furnaces. Dated June 10, 1868.

This invention is not described spart from the drawings.

—Patent completed.

Patent completed.

1889 J. T. LADYMAN, Rochdale. Apparatus for working wood. Dated June 10, 1868.

This invention consists, mainly, in an improved construction, combination, and arrangement of various tools or cutting instruments for working wood in one and the same machine, and refers more particularly to that description of machine known as the "general joiner." The invention comprises much detail, which we cannot produce here.—Patent completed.

1890 W. HAMER, Bowden, and J. DAVIES, Runcorn, Cheshire. Furnaces of sail pans. Dated June 10, 1868.

This invention consists in substituting for that part of the brickwork liable to be affected by the fire vessels, which the patentees prefer to be of wrought-iron plates, riveted or welded together, and so constructed that they may be filled with water. This water prevents the iron plates from being burnt by the fires, and when heated or converted into steam, it may be used for heating other pans, or for other purposes.—Patent completed.

1891 J. Carter, Strand. Portable closet. Dated June 10,

1891 J. CARTER, Strand. Portable closet. Dated June 10,

1891 J. CARTER, SURBLE.
1868.
This invention consists in constructing the seat of or for a commode or water-closet in pieces, and hinging or jointing them together, so that they may fold or pack into a small compass.—Patent abandoned.

1892 C. W. SIEMENS, Great George-street, Westminster.

Manufacture of cast steel. Dated June 10, 1868.

This invention relates to a previous patent granted to the present patentee, dated August 21, 1867. The details of the invention are too voluminous to admit of our quoting them here.-Patent completed.

them here.—Patent completed.

1893 J. and E. Firth, Belfast. Reaping and moving machines. Dated June 10, 1863,
These improvements have for their special object to obviate the necessity of using a crank or cranked shaft for giving motion to the knife bar, the irregularity of the motion imparted through the crank speedily deranging the working parts of the machine, and not unfrequently breaking the knife bar.—Patent abandoned.

1894 C. E. BROOMAN, Fleet-street. Breech-loading five-arns. (A communication). Dated June 10, 1868. This invention is not described spart from the drawings.—Patent abandoned.

-Patent abandoned.

1825 A. M. Clark, Chancery-lane. Pipes used for smoking. (A communication). Dated June 10, 1868.

The patentee claims, first, the application to pipes of an imitation lighted eigar, for the purpose of simulating a cigar and holder. Second, he claims the particular arrangements and mode of filling the artificial eigar to the pipe, for the purpose of removing it when desired, as described.—Patent completed.

pipe, for the purpose of removing it when desired, as described.—Patent completed.

1896 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved apparatus for shuffling and dealing cards. Dated June 10, 1883.

This invention relates to a new and improved apparatus for shufling and dealing cards, and consists in a box made of wood or any other material combined with a clockwork movement. This box having the width or thereshouts of a pack of cards twice its length, and about three times its thickness, is divided at the middle transversely by several steel or copper wires, fixed in its sides at a certain distance from one another. The cards being put into the box furnished with a lid, are shaken in the direction of its length, and are thus shuffled by being divided and separated by the transversal metal wires. The shuffling of the cards being effected by inclining the box, and pressed towards the upper part thereof, by means of a spring placed at the bottom of the box, and which is set free by the hand against a cork or wooden roller, covered or not with cloth or caoutehout. This roller receives a rotation movement from the clockwork placed in an envelope fixed in the upper extre nity of the box by means of ordinary gearing, and this rotation has for its object to carry away and in succession push outside all the cards through an opening or slot at the end of the box.—Patent completed. -Patent completed.

1397 E. P. J. L. FERREL (des Chenes), Villie-Morgon, France. Apparatus for heating wine, &c. Dated June 10,

This invention is not described apart from the drawings.

This invention is not described apart from the drawings.

Patent completed.

1898 W. F. PROCTOR, Glasgow. Embroidery apparatus to be applied to seeing machines. (A communication). Dated June 10, 1868.

This invention relates to the application to sewing machines of the ordinary construction of automatic apparatus, by means of which braiding threads may be lapped around the vertical needle, and made to cross each other in such numerates the way when the described in the contraction of other in such manner that they may be held down on the face of the fabric to be ornamented by means of the stitches formed by the needle thread. The arrangement admits of modification.—Patent completed.

admits of modification.—Patent completed.

1899 W. Barton, Boston, Lincoln. Kitchen ranges. Dated June 10, 1868.

The patentee claims, first, the several arrangements of parts set forth and described, comprising an open fire-place, with one or more boilers and ovens, so arranged as to economize and use the heat given off from the fuel, Second, constructing the boilers with outside vertical tubes communicating with the top and bottom of the boilers, and which tubes being contained in the flue space by the side of the boilers, will receive heat from the gases and flame arising from the fire, and will materially assist in heating the water in the boilers. Third, he claims constructing the ovens with internal flue tubes, for the passage of the heated gases, as set forth. Fourth, forming openings from the space above the range communicating by suitable flues with an annular space surrounding the smoke plpe, for the purpose of carrying off any effluvia or vapours arising from the cooking, and conducting them into the chimney, as set forth.—Patent completed.

1900 C. R. E. Grund. Bow-lane, Cannon-street, London.

into the chimney, as set forth.—Patent completed.

1900 C. R. E. GRUBB, Bow-lane, Cannon-street, London.

Match bor. Dated June 10, 1868.

The box may be formed of thin metal, but, by preference, the inventor makes use of paper or pasteboard. Supposing the body of the box to take the form of a round or oval tube (which will commonly be the shape he employs), he closes opposite ends of the tube by fitting thereto hinged lids, which lids will lie flush, or nearly so, with the periphery of the tube, and he ensures the closing of the lids by connecting them together internally by a band of india-rubber compound. The tension of the rubber will keep the lids closed, and yet allow of access to the box at either end, which will be a great convenience when the box is used for carrying double-ended fuzees. Friction surfaces for the ignition of matches may be prepared on one or both of the lids of the box.—Patent completed.

1901 T. E. Williams, Newport, Monmouthshire. Pots

one or both of the lids of the box.—Patent completed.

1901 T. E. WILLIAMS, Newport, Monmouthshire. Poise employed in the manufacture of tin and other plates. Dated June 10, 1863.

This invention consists in the peculiar shape or formation of the annealing pots, whereby their strength and durability are greatly increased without adding materially to their weight or cost. Instead of making the improved pots square or rectangular in their cross section with straight sides, as such pots have hitherto been constructed, the patentee makes them with curved corners, or with curved sides and corners, the interior of the sides being either convex or concave, according to the nature of the work for which the pots are to be used. The said pots may be constructed of iron, clay, or other suitable material.—Patent completed.

1902 W. H. WESTWOOD. Dudley. Wor cester. Gasholders.

coating or covering with lead, or an alloy of lead, the wrought or east from of which the said gasholders, gas purifiers, and apparatus are made, so as thereby to protect the said wrought or east from from the corrosive action of the sulphur and other matters contained in the gas. The invention consists, second, in the methods of forming the joints of gasholders and apparatus used in the manufacture and distribution of illuminating gas, composed of plates or sheets of iron.—Patent completed.

ture and distribution of illuminating gas, composed of plates or sheets of iron.—Patent completed.

1903 H. Turner, Leeds. Construction of privies, ashpits &c. Dated June 11, 1863.

The fecal matter is collected in a cistern made, by preference, of glazed fireclay, or carthenware, and the urineis conducted by spouts or otherwise into the space beneath the cistern, into which space the ashes are also collected one end of the cistern is provided with a sliding door oraping, and the cisterns are placed so much above theleve of the street or road that the contents may be drawnout by a scraper or otherwise, and collected in a suitableur or vessel. The ashpit is not required to be emptied at the same time as the cistern, as the contents of the cistern are kept separate from the contents of the ashpit. The whole system of privies and ashpits are shut up by a large door, which is only opened by the night soil men, when the cisterns or the ashpit are to be emptied. When the large door is open, the cart or vessel to collect the feeal matter is backed in under the end of the cistern, a small door in the large door giving access to the privies. The privies are ventilated by lines carried from the back of the seat, and taken up to the top of the chimney, or to any convenient part of the building.—Patent completed.

1904 S. Barlow, T. Edmeston, and T. Beeby, Stokehill, near Manchester. Furnaces for steam boilers, &c. Dated

1904 S. Barlow, T. Edweston, and T. Beebt, Stokehill, near Manchester. Furnaces for steam boilers, &c. Dated June 11, 1868.

The furnace consists of two sets of gratebars, the upper set being tubular, and containing water, as described in the specification of letters patent granted to S. Barlow and T. Edmeston, on April 11, 1867 (No 1078), and the lower set is of the usual construction, or tubular, with water passing through them. The tubes of the upper set of gratebars are connected to front and back water chambers, the front one being connected by a pipe or pipes to the lower part of the boiler, and the back one by a pipe or pipes or a water pocket to the upper part of the flue. A bridge is placed above the upper set of gratebars, and another at some distance apart below the same. By this arrangement the products of combustion from the fuel, which is placed chiefly on the top set of gratebars, are drawn down and ignited by the fuel on the lower set of gratebars, and they then rise again through the top set, and then pass over and under the back water chamber to the flue. The water is caused to circulate through the hollow gratebars by the action of the pre-ducts of combustion on the pipe or pipes or water pocket connecting the backwater chamber to the top of the flue.—Patent completed.

1905 W. UNSWORTH, Paris. Sail brake. Dated June 11,

1868.

The patentee claims the employment of a sail brake for stopping trains, either to be used singly, or in conjunction with those now existing, such sail being raised or lowered by means of chains or cords, either by aid of one or more screws, and winged nuts, as described, or by means of a drum and angle toothed pinions, in the manner and for the purposes set forth.—Patent completed.

the purposes set forth.—Patent completed.

1906 J. Rodgers, Hunslet, near Leeds. Bands for driving machinery. Dated June 11, 1863.

The objects of this invention are, first, to produce driving belts, straps, or bands of greater strength and lightness than those in ordinary use. Second, to avoid the annoyance arising from the stretching of ordinary belts when in use; and, third, to obviate the necessity of stretching new belts before use. The inventor accomplishes those results by several means.—Patent abandoned.

1907 A. M. CLARK. Chancery-lane. Bricks' for building, &c. (A communication). Dated June 11, 1868.

This invention relates to improvements in the manufacture of bricks or slabs suited to building purposes from the dross of blast furnaces combined with hydraulic and other limes, cements, or plaster, and it consists in a mode of reducing the dross to a line granular condition by plunging it into water while still in fusion and inean descent, by which means the dross is reduced to a fine sand suited to the purpose required.—Patent abandoned.

1908 S. J. Paris, W. H. Drummond, and D. Hamer,
Manchester. Values. Dated June 11, 1868.
This invention relates to valves which open and close to
control the passage of liquids or fluids, and is designed
for the purpose of diminishing or removing the pressure on
the realings or frictional surfaces of the said valves.—
Patent abandoned.

1909 E. A. SOUTHBY, Lanark. Utilizing eleaginous acid seasts. Dated June 11, 1868.

This invention has for its object the utilizing of the acid waste which is deposited or precipitated on treating any hydrocarbon oil with sulphuric acid, and which acid waste is also sometimes termed acid tar, and pitch, or acid sludge. And the invention consists in suitably heating the waste so as to throw off the sulphur compounds in the form of sulphurous acid gas, which may be used as such, or be converted into sulphuric acid in the usual way—Patent abundoned.

1910 W. Havangeon, C.

abandoned.

1910 W. HENDERSON, Glasgow. Apparatus for finishing woren fabrics. Dated June 11, 1868.

This invention relates to apparatus for finishing woven fabrics of the kind in which the fabric is held, by its edges, upon two endless chains, arranged to carry it through the apparatus, and actuated, in some cases, so as to impart an oscillatory or intermittent movement to the fabric, whereby what is known as the elastic finish is obtained. The invention relates, more particularly, to the holding details, and consists in thing the improved holders or clips directly down upon the top of the links composing the endless chain.—Patent completed.

being either convex or concave, according to the nature of the work for which the pots are to be used. The said pots may be constructed of iron, clay, or other suitable material.—Patent completed.

1902 W. H. Westwood, Dudley, Wor cester. Gasholders, &c. Dated June 10, 1868.

This invention consists, first, in so making or arranging seeing machines that the patentees combine the main cam with the flywheel, and means for imparting foot or services and motion to the same, the combined cam and flywheel working at right angles with a bar that carries the shuttle, and which said bar is actuated by the cam on the periphery of the flywheel, and is supported in its work by a strong of gas for illumination. The invention consists, first, in

frame or body, and top arm of the machine, the said shuttle bar carrying the shuttle as before stated, rendering a shuttle mace unnecessary. The bed bar before referred to they purpose euclosing with a piece of drawn or other tube, which may be of any desirable section, or otherwise, to suit various hands or description of work. Second, the improvements relate to the tension and means of regulating the same, which consists of a thin disc of metal serrated or divided around its edge, each divisional part being alternately spread outwards, so as to form a groove for the thread to ride on, and the serrated disc moves on an axis supported in its rectangular position by a washer, front and back, and regulated by a screw and spiral or other spring, the presence of which against the front washer regulates its action. Third, in applying indiarubber around the groove of sewing machines and driving wheel of the machine stand in which the gut or cord works for the purpose of deadening the sound, as well as for the advantage of its contraction and expansion, and adhesion to the gut or cord while at work. And, lastly, the general combination.—Patent completed.

1912 W. E. NEWTON, Chancery-lane. Cement\_applicable to china, &c. Dated June 11, 1868.

To make the cement, take, say, one pound of white glue which soak in soft water till the glue is dissolved, then add 41b. of izinglass, and 40z, of pulverized gum arabic, 40z, of gum tragacanth dissolved in water, 60z, of white lead, 40z, of bleached gum shellac dissolved in alcohol; after which should be added half a pint of alcohol, and 10z, of best glycerine. The cement or mixture thus produced should be bottled while warm, and the bottle afterwards suitably corked or stopped.—Patent abandoned.

suitably corked or stopped.—Patent abandoned.

1913 J. Lord, Crawshaw, Booth, near Ravenstall, Lancashire. Applying soap, oil, or similar materials to cotton scool, &c. Dated June 11, 1868.

The patentee is aware of revolving rollers having been previously used for the purpose of oiling fibrous materials, and he therefore lays no claim to rollers generally, but he claims, for the purpose aforesaid, the use of a roller partly immersed in the fluid, and taking the said fluid upward to the section of the revolving distributor.—Patent completed.

1914 A. E. G. THENARD, Leicester-square. Apparatus for effecting the combustion of fuel. Dated June 11, 1869. The great length of this invention precludes our quoting it here at sufficient length for an intelligible abstract.—Patent abandoned.

Patent abandoned.

1915 F. WARNER, Jewin-crescent, London. Obtaining scater. Dated June 11, 1868.

The inventor forms a bore hole in the earth, and lines it with a light metal tube in the usual manner, taking care that the earth is closely rammed in around the lining tube at the top. Within the lining tube he inserts a pipe reaching to the bottom of the hole, or nearly so. He prefers that the pipe should terminate a short distance above the water level in the bore hole, so that the first action of the pump may be partially to exhaust the air in the space between the lining tube and the inner pipe; thus an imperfect vacuum is formed which tends both to suck water in to the bore hole, and to aid the pump in its further action. An air-tight joint is made between the lining tube and the pipe, at or near the top of the lining tube and a pump is connected with the Interior pipe, which is thus the suction pipe of the pump.—Patent abandon.d. pipe, which **abandon**ed.

1916 T. MORRIS, Regent-street. Buovs. Dated June 11

1808. The inventor proposes to make floats or vessels possessing considerable buoyancy, and to partially immerse or totally submerge the same as may be necessary for affording supports to objects for erections in or above deep water. He proposes to effect partial or total submergence by the use of cables, chains, rods, or other means connecting the buoyant vessels with weights, anchors, or fastenings resting upon or affixed to the underlying rock or water bed. The main body of the buoyant vessels being kept below the level of more active agitation, would be sufficiently at rest to afford stationary support to objects and erections of comparatively small sectional area, rising to or above the surface of the water, and the degree or quantum of support would be that of the ascensive power of the immersed or submerged vessel or its resistance to further depression.—Patent abandoned.

1917 A. S. STOCKER. Horsleydown, Surrey. Infants'

ance to further depression.—Patent abandoned.

1917 A. S. STOCKER. Horsleydown, Surrey. Infants' feeding bottles. Dated June 11, 1868.

One portion of this invention relates to producing caps or covers out of certain kinds of metal or alloys of a yielding unridged pliant nature, say, block tin, pewter, Britannis, or such like metal, as will readily conform to and receive screws or their equivalents provided thereon or therein by external and internal pressure by the aid of an india-rubber mandril or plug, the plug being in combination with internally screwed dies or natrices made in two parts, and to follow each other with a view to facilitate the release of the caps or covers therefrom, after they have been shaped, as well as for operating upon them with greater rapidity.—Patent completed.

1918 F. D. LA CHASE. Worship-street, Loudon,

greater rapidity.—Patent completed.

1918 F. D. LA CHASE. Worship-street, London.
Governors for steam and other engines. Dated June 12, 1868.
This invention consists, chiefly, in the novel construction and arrangement of the parts of an engine governor, whereby the work of governing and closing the throttle valve is entirely effected by the engine, which, at the same time, is completely under the control of the governor. The latter being relieved from the resistance offered by the friction, and weight of the valve and spindle, is rendered more sensitive to slight variations in the speed of the engine, whose motion is thereby rendered more regular and uniform than has hitherto been practicable.—Patent abandoned.

1919 J. H. JOHNSON Lincoln.

Patent abaudoned.

1919 J. H. JOHNSON, Lincoln's Inn-fields. Miners' safety cages. Dated June 12, 1868.

This invention relates to certain peculiar combinations or arrangements of mechanism for arresting miners' safety cages, lifts, or other like hoisting apparatus, in their descent when the hoisting rope or chain breaks, and consists, essentially, in bringing into action the arresting mechanism of the cage or lift by means of a counter weight in connection with the mechanism by which the cage or lift is arrested in substitution for springs.—Patent completed.

1920 A. L. Herry Tarana.

1920 A. L. HENRY, Trafalgar-square, Charing Cross.
Treating quarts, &c. Dated June 12, 1868.
This invention consists in converting silica or silicates (such as are found in nature, and such as had been produced.

artificially) into sulphide of calcium, by treating them in the way described, with sulphur or compounds of sulphur, and then in treating the sulphide of silicium with water or steam, whereby the sulphide is decomposed, and the silicium converted into a hydrate of silica which is soluble in hot water and is ready for use in the arts and manufactures, as described.—Patent abandoned.

factures, as described.—Patent abandoned.

1921 A. L. FLEURY, Trafalgar-square. Apparatus for treating gold and silver over. Dated June 12, 1868.

This invention consists in mixing powdered gold or silver ore with a proportionate quantity of fluoride of calcium, natural or such as is artificully prepared, or of any other fluorine salt or acid, and exposing this mixture to the combined action of steam and carbonic acid. A decomposition of the mineral results, and a milky solution is obtained from which the mechanically suspended gold is abstracted by passing the liquid through a bath of mercury, or other suitable menstraum. The refuse mineral solution is used as a cementing liquid or base for paint in the way and for the purposes described.—Patent abandoned.

abandoned.

1922 J. Gray and R. Weir. Glasgow. Treating ore. Dated June 12, 1868.
This invention has, principally, for its object the obtaining of steel from iron ores, and from crude metal, but it is also applicable for obtaining from their ores copper, tin, and lead, or for refining these metals. The invention comprises certain means for driving off phosphorus, sulphur, silicon, boron, and other impurities, in a more effectual and economical manner than heretofore.—Patent completed.

1923 J. Anderson, Ramsbottom, Lancashire. Machinery employed for preparing and spinning hard waste or cop-bottoms. Dated June 12, 1868. This invention relates to the preparation of hard waste

This invention relates to the preparation of hard waste which the inventor obtains in continuous carding by dividing the doffing cylinder into two or more spaces forming endless belts of cards on the said cylinder (instead of dividing the cards across the periphery and stripping endwise, as heretofore practised). The cardings pass from the doffer and are received by rollers and coilers into the can motion end can.—Patent abandoned.

1924 G. DAVIES, Serie-street, Lincoln's Inn. Cranca. A communication). Dated June 12, 1868. This invention is not described apart from the drawings. Patent completed.

—Patent completed.

1925 L. and A. PYKE, Holborn. Shirt studs. Dated June 12, 1868.

Here the inventors propose, in lieu of the ordinary back of the stud, that at the end of the neck of the stud or button a back shall be fixed, so as to fold down or lie against the neck on hinges or movable joints, so that, when required to pass through the hole of a shirt or buttonhole, the two halves forming the back may fold down, and after passing through to open flat, and thus form a back, and securely fix the stud in its place.—Patent abandoned.

1925 I W CUTNORE Holloway. American for cooling.

securely fix the stud in its place.—Patent abandoned.

1926 J. W. CUTMORE, Hollowsy. Apparatus for cooling liquids. Dated June 12, 1868.

The stret part of this invention consists in the construction of refrigerators particularly applicable to the cooling of liquids generally, such as water, wines, &c., but more especially to the cooling or Icing of beer as it is drawn from a beer engine. The second part of the invention consists in uniting the pipes or tubes for supplying the apparatus with liquid, or for withdrawing it therefrom, by means of a metal clip slipped over a piece of flexible tubing passing over the ends of the pipes to be joined; the said clip is provided with flanges which are pressed together and held by a nut or screw, so that the clip holds the flexible tubing securely to the pipes.—Patent abandoned.

1928 N. D. SPARTALII, Liverpool. Apparatus for burning

1928 N. D. SPARTALI, Liverpool. Apparatus for burning ydrocarbon oils. (A communication). Dated June 12,

This invention is not described apart from the drawings.

Patent completed.

3637 W. R. LAKE, Southampton-buildings, Chancery-lane. Anchors. (A communication) Dated June 12, 1868.

This invention has for its object the construction of an anchor which shall be cheap and useful, and which may be easily stowed, and can be made to occupy but small space when not in use, while, from its peculiar construction, in whatever way it may fall on the ground or bottom, one or both arms or flukes will immediately take and hold. These objects are accomplished by placing the arms or flukes in longitudinal openings in different portions of the shank, and at right angles to each other, so that the arms or flukes may swing out on either side by gravitation as the anchor falls, while, when not in use, they lie within the body of the shank.—Patent completed.

1929 S. S. Bent, Porchester, New York, U.S.A. Poultry

1929 S. S. BENT, Porchester, New York, U.S.A. Poultry houses or coops. Dated June 12, 1868.

The object of this invention is to make the coop or house, the nests and the feeding pans, wholly or partially of iron, in such a manner as to ensure cleanliness and freedom from the lice and vermin usually found upon chickens and other poultry, and at the same time to protect the poultry from rats, foxes, and other animals.—Patent abandoned.

abandoned.

1930 C. ROSTAING and E. VIVET, Paris. Material suitable for making steam, water, and gas-tight ioints, &c. Dated June 12, 1868.

This invention has for its object an improved material suitable for making water and gas-tight joints, and for similar uses. The patentees take two sheets of wire cloth, of any suitable dimensions and metal, such as iron, copper, or brass; they place between them a sheet of lead, and pass them together through rollers, so as to press the wire cloth into the substance of the lead, and thus form of the whole one and the same body; other suitable means may be resorted to for combining the wire cloth and the lead. The material thus made is placed and passed between the parts or junction of any apparatus for suctaining pressure, such as steam, liquid, or gas pressure, and for preventing the egress or ingress of such steam, liquid, or gas,—Patent completed.

1931 W. RICHARDS, Birmingham. Breech-loading fre-

liquid, or gas.—Patent completed.

1931 W. RICHARDS. Birmingham. Breech-loading frearms and projectife. Dated June 12, 1868.

The patentee claims, as respects one part of the invention, the constructing breech-loading firearms, in which
the breech is closed by a block turning on an axis at right
angles to the bore, the arranging the parts of the lock
within such block and in such manner that the movement of the lever handle to open the breech "cocks" the
lock, or prepares it for the discharge of the piece. He
also claims in such firearms the arranging the extractor

to receive its outward movement from a finger carried by the breech-block on a spring stem, so that the finger is able to pass the nib of the extractor in closing the breech by the outward yielding of the stem. He claims, as respects another part of the invention, in firearms in which the breech is closed by a block turning on a horizontal axis at its breech end, the combining a striker and apparatus for actuating the striker with such block, so as to adapt the gun to receive central-fire cartridges carrying their own priming. He also claims in such firearms the mounting the tumbler within the body or frame on the same axis with the breech-block, and the arranging the hand lever which actuates the breech-block, so as also, in opening the breech, to draw down the tumbler and cause the striker to recede. The specification includes much detail, reference to the drawings being necessary for a full description of the drawings.—Patent completed.

1932 C. HUMFREY, Southwark. Flexible compound appli-tible to waterproofing and other purposes. Dated June 13,

In the manufacture of stearic acid from neutral oils and In the manufacture of stearic acid from neutral oils and fats by what is known as the acid process, a large quantity of residuary pitch remains in the stills after the volatile fatty acids have been distilled over. Each different oil or fat, when submitted to the acid process before mentioned, will leave a different residue, though all similar in chemical residues may be employed for the purposes of this invention, but the inventor prefers the pitch resulting from the acidification and distillation of palm oil. To render these products or pitchy residues fiexible and soluble in any ordinary solvents, such as turpentine, naphtha, petroleum, or coal oil spirits, or mixtures of the same, he mixes them with the residuary pitch obtained in the distillation of the crude oil or tar obtained from Boghead and other oil-producing coals. Any of these may be used with success.—Patent abandoned.

1933 J. Toft, Mauchester. Lathes for turning, &c. Dated

1933 J. TOFT. Mauchester. Lathes for turning, &c. Dated

1933 J. Toff, Mauchester. Lathes for turning, &c. Dated June 13, 1868.

The object of this invention is the construction of lathes for turning or manufacturing in an automatic manner, from sticks, rods, or blocks inserted in the lathe, articles or bodies of regular and irregular forms, including wooden boxes, thread spools or bobbins, tassle moulds, and other articles or bodies of a bollow or solid character, and the invention consists in means and arrangements for effecting this object.—Patent completed.

1934 C. H. MITCHELL, Barhead, Renfrew. Steam engines. Dated June 13, 1868.

This invention has for its object to construct and work

This invention has for its object to construct and work

1934 C. H. MITCHELL, Barhead, Renfrew. Steam engines. Dated June 13, 1868.

This invention has for its object to construct and work steam engines in an improved manner with the view of economizing fuel. The principal feature of novelty is a peculiar mode of combining a high pressure cylinder and a low pressure cylinder with one port face, so that one valve may serve both cylinders, and so that the expansion of the steam which is admitted directly from the boiler to only one end of the high pressure cylinder may be carried to an unusually great extent without the great variation in the strain on the crank shaft associated with ordinary modes of working very expansively—Patent abandoned.

1935 C. Whitehous, Bridgtown, near Cannock, Stafford. Bering bits and augers. Dated June 13, 1868.

This invention consists in making boring bits and augers of a forked-shaped frame or hollow barrel, open on opposite sides, the said frame or barrel being either parallel or taper, and providing the nose or acting end of the said frame or barrel with a helical blade or cutting edge, or helical blades or cutting edges, and either with or without a central worm or point, or leading point, whether the said nose end be convex, flat, or pointed (substantially as described and illustrated). Also in making the boring bit or auger of a half forked frame or barrel, with a helical blade or cutting edge at the nose end, and either with or without a central worm or point (substantially as described and illustrated)—Patent completed.

1936 W. and J. Mackie, Kilbornie, Ayr, North Britain. Steam boilers. Dated June 13, 1868.

This invention consists in forming the flue division at the rear of the boiler of one or more auitably shaped metallic vessels or chambers, in place of a brick wall, as as usually constructed. The feed water is forced by the feed pump through a pipe placed in the flue, and connected to each of the chambers near the bottom. Another pipe is placed over the top of the chamber or chambers and connected to each of the chambers n

1937 W. MULLER and G. ENGLERT, Earl's-court, London.

Apparatus for cooling beer, &c. Dated June 13, 1868.

This invention is not described apart from the drawings.

-Patent completed.

Patent completed.

1938 J. Howden, Glasgow. Steam or other motive power engines. Dated June 13, 1888.

This invention consists, chiefly, in new methods and arrangements for working the valves of steam or other motive power engines, by which the power usually expended in giving motion to the valves is greatly reduced, and the action of the steam, air, gas, water, or other fluid in the cylinder rendered more effective. These improved arrangements are also combined in some cases with a regulating movement in connection with the governors by which a uniform speed is maintained by varying the admission of the steam, air, gas, water, or other fluid in proportion to the amount of work to be done. The invention is not described apart from the drawings.—Patent completed.

1939 W. YATES, Duke-street, Westminster.

Patent completed.

1939 W. YAES, Duke-street, Westminster. Furnaces to be used in metallurgic operations. Dated June 13, 1868.

This invention relates more particularly to those furnaces in which iron and steel are operated upon, and consists in constructing such furnaces, or protecting their inner surfaces, by lining in such a manner that they will be better able to resist the great heat to which such furnaces are exposed in metallurgic operations. In constructing a new furnace, say, a rotary puddling furnace, the inventor forms the cylinder of a suitable number of wedge-shaped bars of malleable cast iron, steel, or wrought iron, which are secured in their place either by being placed inside a casing made of sheet iron, or by means of metal bands or rings, or in any other convenient manner or the wedge-shaped bars may be attached or fixed to end

plates made of malleable cast iron or steel, in which are nade openings for obtaining access to the interior of the ylinder.—Patent abandoned.

oyinder.—Palent abandoned.

1940 K. MALSTER, Pall Mall, Westminster. Compound for cleaning gloves. Dated June 13, 1868.

This mixture or compound is made by immersing fatty acid, dry soda, and chloride of sodium, in water for about thirty-six hours, by then bringing the mixture (by a grinding mill or otherwise) to the consistence of cream or paste, by then adding spirits of wine, and, finally, submitting the mixture a second time to the action of the mill.—Patent completed.

1941 J.T. PARLOUR, Pimlico. Elevators and apparatu for shorelling, raising, and conveying grain, &c. Dated June 13, 1868.

This invention is not described apart from the drawings -Patent completed.

-Patent completed.

1942 P. H. DENNIS, Chelmsford. Horizontal tubular boiler. Dated June 13, 1868.

This invention has for its object improvements in the construction of boilers for the purpose of heating hot water pipes or other surfaces, and consists of a series of cast or wrought iron, or other metal tubular rings, with blocks, sockets, flanges, or other connections at one or more points, by which the tubular rings may be tatached to each other, so that any number of rings may be readily put together to form one boiler, each tubular ring being, by preference, wrought, formed, or cast separately; but, if it should appear more desirable, the whole, or any two or more parts, of the said boilers, which are in the specification described as a separate section or portion, may be wrought, formed, or cast in one piece.—Patent completed.

1943 W. R. LAKE Southamnton-buildings Chancery.

wrought, formed, or cast in one piece.—Patent completed 1948 W. R. LAKE, Southampton-buildings, Chancery-lane. Hulting or securing wheat. (A communication.) Dated June 13, 1868.

This invention relates to a grain hulling or scouring machine, in which a rough surface cone revolves inside of a revolving cone-shaped screening cylinder, but in a direction contrary to that of the latter, into and between which cylinder and cone the grain to be hulled or scoured is fed by a forced feed, and from the chamber containing the said cone and cylinder. The cleanings, scourings, hulls, dust, and other refuse, are drawn by a forced current of air created by a suction fan whilst the cleaned or hulled grain is carried out of the machine at a separate and remote point from where the cleanings or scourings are taken off. The invention is not fully described apart from the drawings.—Patent completed.

1944 E. FISHER, Camberwell. Tonic efferencing drink.

the drawings.—Patent completed.

1944 E. Fisher, Camberwell. Tonic efferesting drink.
Dated June 18, 1868.

Here the inventor proposes to employ the tonic bitter extract of orange, or other similar tonic extract, from flavoured fruits, and to mix therewith a syrup in such proportion to sult the taste; these materials, being compounded, are to be placed in champagne bottles, or other strong bottles, after which filtered water is forced in by means of the champagne cone, and the bottle is tightly corked and secured.—Patent abandoned.

corked and secured.—Patent abandoned.

1945 C.E. SCHWARTZ, Hoxton. Obtaining crystal brocatel colours. Dated June 13, 1868.

Here the inventor prepares new crystal brocatel colours from mica (Brotel Muscowity, also called "cat selver." For this purpose he takes the raw material, which, when mixed with earthy or iron particles, he breaks into pieces, and purifies by digestion or boiling in hydrochloric acid. It is next freed, by washing, from any acid that may adhere to it, and then dried. The mica thus purified he exposes to a red-hot heat until it has acquired a beautiful silvery glitter. It is then ground down, when in a wet state, between mill stones, or crushed under rollers, or put into a stamping mill in a dry state, and bruised into variously sized lamina, which are sorted by being passed through a sieve or sifting machine, and numbered according to the different sizes. The silver colour thus obtained may be variously tinted by a combination with different colours.—Patent abandoned.

1946 J. Ball, jun., Nottingham. Apparatus employed in

1946 J. Balt, jun., Nottingham. Apparatus employed in the cutting off the superfluous portions of threads from spots, sprigs, figures, or other devices made on lace or other fabrics. Dated June 13, 1868.

special prices of the derical portions of threats from spots, sprigs, figures, or other derical made on lace or other fabrics. Dated June 13, 1868.

Here standards carry bearings for a driving shaft, on which are a fast and loose pulley, and whence motion is transmitted to a shaft carrying knift blades placed at an angle to its length, and radiating from it. Each blade is plain on one side, and scrated on the other. The driving shaft, also, through a second driving shaft, works a roller over which the lace or fabric to be operated upon is passed, having previously passed over another roller. Both rollers are covered with wire carding, and they receive the lace or fabric from between two other rollers, one of which is carried by bearings capable of being turned outwards to readily receive the lace or fabric; above the first wire card roller is a brush driven from the second driving shaft to raise or brush up the superfluous threads from the surface of the lace or fabric provious to its reaching the knife roller, under which it passes; it also passes under a sharp stationary knife. This knife and knife roller are adjustable vertically and horizontally, and with the brush roller can be raised clear of the central standards by a hand lever or equivalent to enable the lace or fabric to be passed back over the lower rollers. The lace or fabric as it passes under the sharp knife will pass over a bar or bridge which supports it while being cut, and it is drawn through the outting machine by passing it between rollers, whereof the lower is driven by the second driving shaft. The lace or fabric when being operated upon may be passed diagonally through the machine from selvage to selvage; the knives and brush roller being raised, the lace or fabric is drawn back for a fresh portion to be operated on.—Patent abandoned.

the chemical formula of which is C 6 H 8 O 6 H O, that is to say, it contains six equivalents of sypil, eight equivalents of hydrogen, six equivalents of oxygen, and one equivalent of water. It is produced by simultaneously casting on incandescent coke contained in a retort heated to a red heat—first, a mixture of water and glycerine; and, second, a jet of olein oil, or carburetted hydrogen, the proportions of which would vary according to the degree of richness or of lighting power desired.—Patent abandoned. doned.

doned.

1949 F. Worgester, Stoke. Tuyers for furnaces. (A communication). Dated June 15, 1868.

The patentee claims, first, the combination with a tuyere or tuyeres of an air chamber or box constructed and arranged substantially as and for the purpose described and illustrated in the drawings. Second, passing the air blast before reaching the tuyere or tuyeres through a water reservoir employed for producing a circulation of water through the said tuyere or tuyeres, substantially as and for the purpose described and illustrated in the drawings. Third, the combination of a hollow tuyere (or tuyeres) with a reservoir, and water and steam pipes, and with the air chamber and parts connected therewith, substantially as and for the purpose described.

—Patent completed.

1950 J. S. Benson and J. Von der Poppenburg, Bir-

—Patent completed.

1950 J. S. BENSON and J. VON DER POPPENBURG, Birmingham. Breech-toading firearms. Dated June 15, 1868.

This invention has reference to those kinds of breech-toading firearms in which the breech end is opened for loading and closed for discharge by means of a block hinged to the side of the breech chamber or shoe, and the invention consists of the improvements described in extracting the exploded cases of the cartridges from the barrels of the firearms, and in holding the breech-block of the firearms in its open or closed positions respectively.—Patent abandoned.

1951 T. KENDRICK, Birmingham. Ornamentation of fenders, &c. Dated June 15, 1863,
This invention consists in the combination of ornamental lacquered brass tubing with ordinary cast iron in the manufacture of fenders, the brass tubing being applied to the parts technically known in the trade as the "bar," the "bead," and the "moulding."—Patent abandoned.

1952 J. H. Johnson, Lincoln's Inn-fields. Zincing baths. (A communication). Dated June 15, 1868.
This invention relates to the zincing of articles of iron or other metal by immersing them in molten zinc, and consists of a zincing bath composed of an outer casing of iron lined with copper or equivalent material for preventing the formation of a dross from the iron and zinc which tends to destroy the iron vessel and renders a great portion of the zinc unfit for coating purposes.—Patent abandoned.

1953 C. HUMPREY, Southwark, and W. S. WEBSTER, runswick-square, London. Waterproofing paper, &c.

1953 C. HUMPREY, Southwark, and W. S. WEBSTER, Brunswick-square, London. Waterproofing paper, &c. Dated June 16, 1868.

By this invention the patentees make the paper waterproof by first saturating the paper itself with any suitable waterproofing solution, and then removing the superfluous solution from the surfaces of the paper by passing it between a pair of wiping surfaces constructed and arranged substantially as described.—Patent completed.

substantially as described.—Patent completed.

1954 W. C. SILLAR, Cornhill; R. G. SILLAR, Upper Norwood; and G. WISNER, Camberwell. Deodoriting and purifying sexage, &c. Dated June 15, 1868.

Here the patentees add to the sewage to be purified a mixture consisting of the following ingredients, viz., alum, blood, clay, magnesia, or one of its compounds, by preference the carbonate or the sulphate manganate of potash or other compound of manganese, burnt clay, otherwise known as ballast, chloride of sodium, animal charcoal, vegetable chareoal, and magnesian limestone. Of these substances the manganese compound, the turnt clay, chloride of sodium, and magnesian limestone, may be omitted, and it is not essential that both animal and vegetable charcoal should be used. If any of the ingredients named should, from any cause, be present in sufficient quantity in the sewage, it may, of course, be omitted from the mixture. The proportion in which the ingredients are to be used vary according to the nature of the sewage to be purified.—Patent completed.

1955 L. B. Pringle, Litchfield, Connecticut, U.S.A.

1955 L. B. PRINGLE, Litchfield, Connecticut, U.S.A. onstructing chairs and rails which form continuous rails for ultroads. Dated June 15, 1868.

Constructing chairs and raus which your railroads. Dated June 15, 1868.

The patentee claims so constructing rails of iron or steel with longitudinal grooves and bevol faces to be put together, and their accompanying chairs, so that, when the two sections or double rails are placed together and secured in their seats, ultimately breaking joints or lapping by each other midway, they form a continuous rail or jointless track for railroads for any desired distance, substantially in the manner and for the purposes specified.—Patent completed.

1956 W. and O. BROOKE, Manchester. Healds or heddles.

Patent completed.

1956 W. and O. BROOKE, Manchoster. Healds or heddles.
Dated June 16, 1868.

This invention relates to a mode of constructing healds, in such manner that each eye for the warp thread will be formed of metal, so arranged that the flat sides of the metal eyes will romain parallel, or nearly so, with the line of the warp threads, and so connected or attached to the material by which they are suspended and actuated, that the ends or edges of the metallic eyes will be prevented from catching upon the adjoining warp threads when working.—Patent completed.

the cutting machine by passing it between rollers, whereof
the lower is driven by the second driving shaft. The lace
or fabric when being operated upon may be passed diagonally through the machine from selvage to selvage; the
knives and brush roller being raised, the lace or fabric is
drawn back for a fresh portion to be operated on.—Patent
abandoned.

This invention consists in a collar constructed with a
waterproof and desiccative or medicated covering, where,
when in use, it is to bear against the surface of a horse or
other animal to which it may be applied. This lining the
patentee usually makes of strong cloth, such as canvas or
kersey, for instance, and a coating of vulcanized caout
chouc or gutta-percha containing sulphur, or other proper
medicament, the coating being applied to the cloth so as
to adhere firmly thereto.—Patent completed.

1948 L. S. THOMMASSIN, Paris. Apparatus for producing
combustible and tiluminating gas. Dated June 15, 1868.
The subject of the present invention is a combustible
and lighting gas, or carburetted hydrate of oxide of sypli,

1958 R. WAPPENSTEIN and R. BAY, Manchester. Apparatus for registering the number of passengers travelling in or on omnibuses, &c. Dated June 16, 1868.

For omnibuses the inventors employ for each journey or stage of the journey a double meter for the inside, and another double meter for the outside, one division of each meter being used for indicating the entrance, and the other the departure of the passengers, and in one or more conspicuous positions they place deals and fingers to be used as check or tell-tales.—Patent abandoned.

used as check or tell-tales.—Patent abandoned.

1959 D. ELDER, Newcastle-upon-Tyne. Dredging machines. Dated June 16, 1868.

The object of this invention is to facilitate the sinking of cylinders or caissons for the foundation of bridges and other works, where ground has to be removed from below the level of water, or for shafts or other similar excavations where earth has to be raised vertically; also for excavations where earth has to be raised for docks, canals, or similar objects. The nature and description of the invention consists in the application of an endless chain of buckets, driven and carried by apparatus fixed on a turntable, which is made to rotate upon a foundation plate temporarily fixed on the top of the cylinder or caisson to be sunk, or over the shaft to be excavated. In operation the apparatus has to be removed when a length of cylinder has to be added, and extended to the required length when replaced.—Patent completed.

1960 T. WHITEHAD, Holbeck, Leeds. Machinery for

1960 T. WHITEHEAD, Holbeck, Leeds. Machinery for combing wool, &c. Dated June 16, 1868. This Invention consists in the application of nipper rollers or other holders to any description of combing machines known or used in the combing trade.—Patent abandoned.

machines known or used in the combing trade.—Fatent abandoned.

1961 J., J., and J. Beoth, Rodley, Leeds. Apparatus for the cutting or dressing of stone, &c. Dated June 16, 1863.

This invention relates, first, to when using lever holders for the cutters used in the cutting or dressing of stone, to giving motion to such cutters by mechanical means, so that the opposite sides or cutting edges of them may be used alternately. Second, the improvements relate to means of giving support to thin slabs of stone during the action thereon of the cutters. Third, the improvements relate when series of tables carrying stone to be cut by suitable cutters are caused to travel round a centre of motion, to causing such tables to be actuated so that the stone thereon may move to the action of the cutters acting thereon in straight or other lines, diverging from a direct circular motion, so as to afford facilities for varying the character of the cut produced. Fourth, the improvements relate to giving vibratory or alternating transverse motion to tables carrying stone during the cutting thereof by suitable cutters. The invention is not described in detail apart from the drawings.—Patent completed.

1962 M. Dramar, Paris. Dial or indicating needle case

1962 M. DEMMAR, Paris. Dial or indicating needle case Dated June 17, 1868.
This Invention is not described apart from the drawings.
—Patent completed.

1963 J. P. WILLS and E. H. CARDELL, South Petherwin, fornwall, and T. F. WILLS, Princes-square, Bayswater, pparatus for mowing or reaping grass, &c. Dated June 17,

1868. Instead of the reciprocating knives now employed in such machines, the inventors use revolving cutters, serrated at the edge, or otherwise adapted to the cutting of straw or grass, and of any convenient shape.—Patent abandoned.

1964 D. MITCHELL, Macclessield, Cheshire. Manufacture of figured cloth. Dated June 17, 1863.

The nature of this cloth is that it is a single and solid cloth with neither weft nor warp, and the figure is raised without wadding or stuffing. And the manner in which it is to be parformed or wovon is in the manner described in detail in the specification.—Patent completed.

in detail in the specification.—Patent completed.

1965 G. B. TURRELL, New York, U.S.A. Coolers for beer, &c. Dated June 17, 1868.

The patentee claims, first, a cooler for beer and other liquids, formed of a series of flattened tubes, with their longest diameters horizontal, substantially as specified, so that the strata of liquid passes in the manner described; and, second, he claims the employment in coolers for beer and other liquids, acting in the manner described, of tubes, rods, or bars, to eccupy the centre of the tubes, the water being caused to pass through the space left between the outer tubes and the tubes, rods, or bars occupying the centre thereof, substantially as shown and described.—Patent completed.

Patent completed.

1966 W. Betts, Hastings, Sussex. Apparatus for weighing carriages, waggons, carls, &c. Dated June 17, 1863.

This invention consists of two springs of elliptic, semi-elliptic, or other convenient form, fixed either separately on two trostles, or on a stand sufficiently long to receive a carriage or vehicle. A graduated bar as an indicator passes through the trostles or stand, such indicator being marked with notches and figures to register the weight of the carriage by the deflection of the two springs, adding the sum of the two indicators together, or connecting the two indicators, and thus reading off the weight at once. The inventor also uses a dial, as registering the weight placed upon the springs. On the top of each spring is fixed a block or cushion, on which the axiotree of the vehicle rests, so that the carriage may be entirely suspended, and the weight correctly ascertained as registered by the indicator.—Patent abandoned.

1967 T. COMFIELD, jun., Ohigwell, Essex. Brakes for

by the indicator.—Fatent sonationed.

1967 T. COMFIELD, jun., Chigwell, Essex. Brakes for railway carriages. Dated June 17, 1868.

An extension of time for filing the final specification of this invention having been grunted, the documents relating to the invention cannot at present be seen.

lating to the invention cannot at present be seen.

1968 J. M'LEOD, Renton, Dumbartonshire. Apparatus for dyeing yarns. Dated June 17, 1868.

This invention has for its object, by means of improved apparatus, to secure the dyeing of yarns in a more uniform and satisfactory manner, and with less manual labour than heretofore. The principal features of novelty in the improved at paratus are the arranging of a number of poles for carrying and working the yarn hanks upon sliding bars made to reciprocate horizontally, and the applying of gearing to turn the poles so as to gradually move round and change the positions of all parts of the hanks.—Patent completed.

1969 W. CARR, Manchester. Construction of hinges ap-licable to the doors of carriages, coaches, &c. Duted June 17, plicable to the

This invention relates to hinges employed for the doors f carriages, coaches, landau, barouches, and other

rehicles, and is designed for the purpose of enabling the door be opened to the full width of the doorway, and to hang vertically when open, and when closed the hinge to arranged within a box that water cannot enter into the woodwork of the carriago frame.—Patent abandoned.

so arranged within a box that water cannot enter into the woodwork of the carriago frame.—Patent abandoned.

1970 J. C. WALKER, Surrey-street, Strand. Baking 1970 J. C. WALKER, Surrey-street, Strand. Baking 1970 determined to be employed in the treatment of four in the manufacture of bread. Ac. Dated June 17, 1868.

The object of this invention is to produce a baking The object of this invention is to produce a baking the training the produce of the produce of the manufacture of light bread. Amylaceous matter the manufacture of light bread. Amylaceous matter which is insoluble in water may be dissolved in concernic trade hydrochloric, phosphoric, sulphuric, or nitric acid trade hydrochloric, phosphoric, sulphuric, or nitric acid trade hydrochloric, phosphoric, sulphuric, or nitric acid rated hydrochloric, phosphoric, sulphuric, or nitric acid rated hydrochloric, phosphoric, sulphuric, or nitric acid rated if solved by one of these acids greatly diluted, at readily dissolved by one of these acids greatly diluted, at readily dissolved by one of these acids greatly diluted, at readily dissolved to of the amylaceous matter is acid its of remains unchanged, the amylaceous matter is acid its of remains unchanged, the amylaceous matter is acid in account of the photocose as pecies of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, a species of resombles gum arabic, and next into glucose, as pecies of resombles gum arabic, and next into glucose, a speci

farinaceous food.—Patent abandoned.

1971 W. and J. RHODES, Braiford. Construction of safes, strong frooms, &c. Dated June 17, 1863.

This invention consists, principally, in the use of strong This invention consists, principally, in the use of strong are of iron, made of such a form, and placed in such a brais of iron, made of such a form, and placed in such a manner, in connection with a secret hinge to the door, as manner, in connection with a secret hinge to the door, as sible, to break open. A furturer improvement consists in the use of a Lewis and wedge, or dog and wedge arrangement, to act as a locking bolt for binding or connecting ment, to act as a locking bolt for binding or connecting to a sunder either by a wedge or screw; also cannot be force of as sunder either by a wedge or screw; also in so coupling the front bars of the safe to the outside plates thereof that they cannot be forced off by a wedge or other instrument.—Patent completed.

1972 A. M. CLARK, Chancery-lane. Purification of

or other instrument.—Patent completed.

1972 A. M. CLARK, Chancery-lane. Purification of ceramic, ritrifable, and other matters. (A communication). Dated June 17, 1868.

Purifying matters used in the manufacture of glass, Purifying matters used in the manufacture of glass, crystal, porcelain, or china, and also enamels, kaolin, phosphates of line, feldspath, and generally all primary inters containing iron in the form of oxide or other satts matters containing iron in the form of oxide or other satts freolouring the same or liable to tinge the matters after their transformation which iron it is desired to eliminately the said of hydrochlorate of ammonia, or a suitable by the said of hydrochlorate of ammonia, with which ties ammoniacal saft, or it may be ammonia with which ties incommoniaced in a volatile form, all in the manner described.—Patent completed.

1973 W. THOMSON, Normanton, York, and J Choserve.

described.—Patent completed.

1973 W. THOMSON, Normanton, York, and J. CROSSLEY, jun., Barrow-upon-Soar, Laucashire. Rails and chairs for jun., Barrow-upon to consists in constructing reversible rails. This invention consists in constructing reversible rails for railways, and the chairs for such rails, in such manner for railways, and the chairs for such rails, which is downwards, that the wearing face of the rail, which is downwards, will not become worn or indented by the chairs. For this will not become worn or indented by the chairs. For this will not become worn or indented by the chair of such form that the rail rests on the bottom of the chair at one side, and on the top of the chair at the other side, one edge of the top, and one edge of the bottom of the rail being suitably shaped for this purpose.—Patent abandoned.

being suitably shaped for this purpose.—Patent abandoned.

1974 J. and E. LUMLEY, Kirk Hamerton, Yorkshire:

Machine for the manufacture of pills. Dated June 18, 1863.

Here a suitable framing supports three rotating cylinders. Here a suitable framing supports three rotating cylinders having grooves formed around their peripheries. Two of having grooves formed around their peripheries. Two of ingredients into the machine and partly divide it lengthed in the said cylinders being of equal diameters; the mass wise, the said cylinders being of equal diameters; the massive the diameter of which is about double that of the cylinder, the diameter of which is about double that of the cylinder. An adjustable curved guide-aforeasid smaller cylinder. An adjustable curved guide-formed in the same guide-piece, corresponding with the formed in the same guide-piece, corresponding with the formed in the cylinders. The knife, after having entirely divided the mass crosswise, conducts it between the guide and the cylinder, and ensures its being taken hold of thereby, and the cylinder, and ensures its being taken hold of thereby, and rolled into pills which fall into a receptacle. Combs are adapted to the grooves of the cylinders for preventing are adapted to the grooves of the cylinders for preventing are adapted to the grooves of the cylinders for preventing are adapted to the grooves of the cylinders for preventing are adapted to the grooves of the cylinders for preventing are adapted to the grooves of the cylinders for preventing are adapted to the grooves of the cylinders for preventing are adapted to the grooves of the cylinders. Combs are defined for imparting rotary motion to the machine.

Patent completed.

#### ELECTRICITY AND TELEGRAPHY FOR 1868.

IN concluding our remarks upon the above subject, we may first observe that a gth of 500 miles for an alternative section in the Persian Gulf has been manufactured by Mr. Henley, at Woolwich, and will in all probability be sent out during the course of the present month. The insulating medium in this cable was also Hooper's material. The Indian Government, having so favourable an opinion of this material from previous trials, determined on its use. The adoption of this material in two such long lengths will, in the course of a few years, undoubtedly set at rest the question of superiority between it and gutta-percha, and more especially with regard to their adaptability for hot countries. Mr. Henley has also manufactured some length of cable for the Danish Company, to be laid from the Danish coast, across the Baltic, to the island of Bornholm, and from there to Liban, in Russia. and from there to Liban, in Russia. A portion of this eighty miles of two-wire cable from Denmark to Bornholm has just been laid; the remainder, a length of 240 miles, has not yet been laid, the severity of the weather having prevented the ship from accomplishing the work.

The India-rubber, Gutta-percha, and Telegraph Works Company manufactured at their works at Silvertown a cable for the American Company, to be laid between Cuba and Florida, as a duplicate of that already down. The length was about 105 miles, and the work of laying undertaken by Sir Charles Bright; in paying out the cable the Gulf Stream proved too strong, so that when they got close to the Cuban shore, in addition to being carried away to leeward of their landing place, they ran short of cable, and lost the end in buoying.

After numerous attempts, partly successful and partly otherwise, the expedition returned. Sir Charles Bright has gone out again lately with more cable to endeavour to recover the end of the cable and complete the communication. In the interests of telegraphy, we trust he may be successful, and that early in the year we may be able to announce the successful completion of the work. The Silvertown Company also manufactured a length of thirty-three miles of massive cable for changing the landing-place of the Zandvoort cable from Dunwich to Lowestoft. This work was successfully accomplished during the summer. A length of old Hague cable was covered by them for resuscitating the communication with the Isle of Man, which has lately been done. In addition to the above, a cable of 200 miles in length has been manufactured for Tasmania at Mr. Henley's works at North Woolwich for the Telegraph Construction and Maintenance Company. This cable will leave early in January under the charge of experienced hadds

As a proof of the great extension of sub-marine telegraphy, the following details of the amount of cables manufactured at the different works will be satisfactory:—Telegraph Construction and Maintenance Company-Malta and Alexandria cable, 960

pany-Cuba and Florida cable, 104 miles extra cable for same place, 15 miles; Lowes-toft and Zandvoort cable, 33 miles; Isle of Man cable, 12 miles; total, 164 miles. Grand total, 3,289. A grand total of 3,300 miles cannot but be considered as a great result for the year's work. Compare this with the preceding year, and all doubts as to progress will at once vanish.

We are glad not to be able to announce the demise of any member of the important cable family. Accidents will happen, and cables, unfortunately, are not free from themwitness the 1866 Atlantic cable, which was broken in two places about eighty miles from Newfoundland. Owing to there being no ship appointed to the station, although there is some talk of the matter, the repairs were not completed until two months had elapsed.

The Wexford cable has been broken and repaired, as also the Lowestoft and Zandvoort cable, the repairs in both cases being speedily effected. The cables also across the traits of Dover have frequently suffered, but communication by that route, though endangered, has never been totally interrupted. In each case the damaged cable was quickly restored to communication. The cable between Malta and Sicily has been broken and repaired, and the cable between Sicily and the African coast has been restored to communication.

The Persian Gulf cable has been interrupted on three occasions, but thanks to having a repairing ship on the station, the interruptions were not of long duration. Owing to the same wise precaution of having a repairing ship, the breaksdown of the Malta and Alexandria shore line were not of great length.

A convention of various telegraph admi-A convention of various telegraph aumnistrations was held during the year at Vienna, for altering the existing rules and for lowering the tariffs. The advantage of the latter has already been perceived.

The increased introduction of automatic telegraph instruments is one of the features of the year. A new instrument has been used in France. In this, it is necessary to mark the transmitting band with insulating marks; the receiving instrument records with In England, Sir C. Wheatchemical marks. chemical marks. In England, Sir C. Wheat-stone's automatic instrument has been much used. The transmitting band is perforated by a machine worked by hand, and signals are received at the distant end in the usual Morse code, either by embossed or ordinary ink dots and dashes.

A new feature in telegraphy has been introduced in France, by permitting telegrams to be sent to lighthouses and various coast stations for vessels at sea. The telegrams received are forwarded to the ship by the usual system of flag signalling. The introduction of telegraph stamps into France dates from the present year, and it will not be unlikely that their example will be followed by other countries who do not use them. The use of stamps with us dates many years back.

Sir William Thomson has introduced a marvellously delicate recording instrument, an illustrated description of which appeared in our columns, but at present we are not aware of any practical adoption of it. The use of his electrometer is becoming very general where delicate tests of submarine cables are required to be taken. It is a most valuable addition to his reflecting galvanometer. By the aid of these two, almost all the necessarily useful and accurate tests of a cable can be taken.

Several improvements in batteries have

who, upon this subject, appears to be indefatigable. His investigations are most interesting.

Electricity has added another to its many characters; it has, during the past year, been successfully used for playing upon pianos and organs. It continues to play its part with increasing success in providing communication between passengers, guards, and drivers of railway trains. In railways altoelectricity is now indispensable; electric signalling, being received with more confidence, is largely on the increase

In literature, the past year can only boast of "Frictional Electricity," a posthumous work of the late Sir W. Snow Harris. This may be looked upon as a valuable work. electricians and telegraphists are largely indebted to two books out last year—Culley's "Handbook of Telegraphy," third edition, and Latimer Clark's "Electrical Measurement."

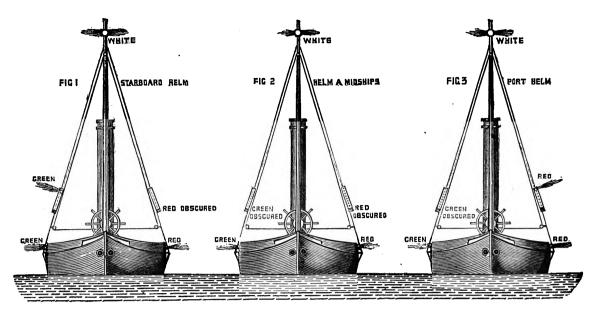

There are many more items of electric and telegraphic progress that, had we space, we might mention; however, enough has been brought before our readers to prove that, with the age, electricity and telegraphy are marching rapidly on, and doing their part well and worthily in the work of human en-lightenment. On the whole, reviewing the work completed and in process of completion, new facts brought to light rendering more clear the mysteries of this intricate science, we are irresistibly drawn to the conclusion that the work so far has been successful, that telegraphy is gradually, and with safe and sure steps, marching on; and that, while there still remains much to be done in the difficult task of clearing the mists from the science of electricity, much has been accomplished during the year to render these mists less opaque, and we doubt not that in the course of time, by dint of the application of mind, assisted by careful experiment, many intricacies in this subtle science will be removed, and the problem of electricity will be simply and satisfactorily solved.

#### JAMES CHALMERS.

WE last week briefly referred to the death of Mr. James Chalmers, whose system of constructing targets promised well for the fortifications of our country. We now place before our readers a sketch of his life, which we know will be read with interest by all.

James Chalmers was one of a number of persevering energetic Scotchmen who, at their outset in life, have possessed little beyond the ordinary education and training, coupled with the indomitable spirit of their country. native of Perthshire, his early days were devoted to gaining his livelihood in one of the branches of the mechanical arts. After some years passed in this country, he resided for some time in Canada and California, and finally settled in London in the early part of 1861. During that year he devoted himself almost entirely to a project for a railway be-tween England and France, with a view to avoid the break formed by the Channel, between the railway system of this country and the Continent. His plan was to have a tube of boiler plate iron, lined with brick work, laid on the bed of the sea, with ventilating towers at intervals; and the pamphlet which he published on the subject attracted general attention, and no small amount of criticism at the time. He exhibited his plans at the International Exhibition of London, 1862, and Paris, 1867, but the amount of capital required, and the difficulties attending so novel and grand a work, have hitherto premiles; Tasmanian cable, 200 miles; for Crown colonies, 5 miles; French Atlantic cable, about 700 miles; total, 1,865 miles. #### READ'S HELM INDICATOR.

many men of first-rate engineering talent, both in France and Britain, have propounded their different schemes for the same object, not one of which has yet been carried into effect, or perhaps ever been subjected to a proper examination. During 1861, various proposals for building ships of war wholly of iron, of iron protected by heavy armour plates, or of effectually protecting wooden-built ships, occupied the attention of the Iron Plate Committee and numbers of scientific and volunteer inventors. Mr. Chalmers was present at a trial which took place at Shoeburyness, in March, 1862, of a target proposed by Mr. Fairbairn, of Manchester. The result of that trial was the destruction of the Fairbairn target, and an examination of the ruins of other targets on the ground, and some in preparation, inspired Mr. Chalmers with the idea that he could improve upon all of them, and he forthwith devoted much of his time to carrying out this idea. Inventors are not always possessed of capital, and the Iron Plate Committee had no funds to assist them—at least, none to give to inventors outside the official circle; but they would give a trial to a target at the inventor's expense. However, Mr. ('halmers, by the kind assistance of Sir S. M. Peto, had one constructed under his own supervision, and it was tried at Sheeburyness in the early part of 1863. The result was that it resisted the shot of the artillery of that time better than any other that had been tried. Since then, the size and power of guns have both been increased, and the Palliser chilled shot have further added to the destructive effect of the guns, when compared with the shot formerly in use. In the mean time, Mr. Chalmers had the mortification to see many of the essentials of his invention copied and embodied in the recent additions to the Navy, without either acknowledgment or compensation; and, notwithstanding all his endeavours, was never able till lately to prevail on the Government to get another target built embodying his invention, to be tried against a Government shield of the same size and weight of metal. In pursuit of this object, and wearied by official delays, his constitution gave way, and during the last eighteen months his health had been far from good, till at last he died on Saturday, December 26, at his residence in Haverstock-hill, London. Let us hope that although he has not lived to witness the success of his new target, the Government will do substantial justice to his memory, and account to his family for any use they have made or may hereafter make of the principles embodied in the Chalmers target.

#### READ'S HELM INDICATOR.

TOTHING can realize so clearly the perils of navigation, and the loss of life from time to time sustained, as a glance at the wreck chart of the Board of Trade. The Goodwin sands and other dangerous portions of our coast are thickly dotted with the fatal crosses; in more open waters more thinly scattered, but marking with more bitter meaning the recklessness, the inattention, the want of security for that sacred possession—human life. The daily papers bring before the public, more or less frequently, instances of wreck and loss of life, which are talked of and forgotten. But in the wreck chart the consolidated evidence of wholesale death is spread out before us. Collisions at sea, so frequent in their occurrence, have yet a sameness in their character which is likely to astonish those who are only casual observers of their cause. On the finest nights, in fog, in storm, and in calm (as when the "Amazon" and "Osprey" came into collision), with a distance of five miles or only of five hundred yards between them, two vessels, seeing each other's lights, bear down upon each other to destroy or be destroyed.

No system of signals, however perfect, can insure the safety of a vessel against the drunkenness of her captain or the insubordination of her crew; and while the recklessness in regard to life, so often characteristic of those who are constantly at sea (whose familiarity with its dangers appears to have created a contempt for its power) exists, collisions will, as a natural consequence, But this is no reason why every care occur. should not be taken to lessen the great total of calamities, and, by a simple and comprehensive code of signals, leave the officer in command without the shelter of the excuse which a contradictory and imperfect system of signals must afford. The defect in the existing code of signals is obviously this—the intention of vessels is not perfectly defined by their lights, and thus the two following articles of regulations for preventing collisions at sea are misapplied. Art. 13 enacts that:

—"If two ships under steam are meeting collisions at sea are meeting to the desired and the steam are meeting." 'end on,' or 'nearly end on,' so as to involve risk of collision, the helms of both shall be put to port, so that each may pass on the port side of the other." Again, at Art. 14, we find -" If two ships under steam are crossing so as to involve risk of collision, the ship which

Holland to Sir John Pakington will illustrate the consequences likely to arise from a misinterpretation of these rules:—"Suppose a vessel, A, has another, B, on her starboard bow, does not the obligation to 'port her helm' put A across the path of B? At times, too, when in darkness or fog, it is impossible to judge of distance, or to know the precise direction of an approaching ship's head, or which way she is steering. At present, it is impossible for two approaching vessels to know when to act under the same rule. A may think that B is 'end on,' or 'nearly end on'; B, on the other hand, may have A two or three points on the starboard side; so the one acts in accordance with Art. 13, and the other follows the instructions of Art. 14, and a collision ensues."

The object of the helm indicator, invented by Mr. George Read, R.N., of the Coastguard, Deal, is to remedy this. In this apparatus an endless line, being taken three coils round the drum of the wheel, passes from thence in an horizontal direction to a pulley on the port side, as shown on the diagram, then proceeding in a vertical direction it goes through a pulley at the masthead, and returns by the starboard side in the same manner to the drum of the wheel. Two lines (dotted on the diagram) pass from this endless line, and are secured severally to the port and starboard lights. The lights are placed in metal tubes, a box at the bottom of each tube concealing the light from sight until, by the vessels being put "to port" or "starboard," it is raised by the movement of the wheel to a higher position in the tube. Only one of the moving lights can, therefore, be visible at a time when the vessel is hard a-port or hard a-starboard, for when the helm is amidships, or the vessel pursuing the course of a line drawn straight along her keel (fig. 2), the two lamps are in equilibrium and totally obscured from sight. Starboard helm raises the green light from its box (fig. 1), and the red sinks out of sight. Port helm raises the red and obscures the green (fig. 3). Retainred and obscures the green (fig. 3). Retaining, therefore, the present fixed port and starboard lights, their relative positions with each other and with the moving lights will indicate the exact position of any vessel at sea. It matters not from what direction she may be coming, as they will show to her the position of any one she may approach. For instance, if A is approaching B end on, or nearly end on, and steering hard a-port, she will show to B two red lights and one green. will show to B two red lights and one green; has the other on her own starboard side shall keep out of the way of the other." The (following out Art. 14), and puts her helm following extract from a letter from Mr. hard a-starboard, she will show two green

lights and no red; if the contrary is the case, she will show two red lights and no green.

At the back of the tube are five holes one over the other, so that the height of the lamp in the tube, and consequent position of the ship, is indicated, not only to the man at the wheel, but to any one on board. If, in the case of collision, the officer in command should be in error in following out the regulations laid down, the tubes being (with the exception of the boxes) entirely open at front, this apparatus will form a register, so that it will require a very unanimous system of perjury (a crime not altogether unknown in Board of Trade inquiries) to overthrow. It will also indicate to vessels approaching from behind the course the foremost vessel is pursuing.

In reference to sailing vessels, an objection has arisen as to squaring the vessel's head sails to obviate this. Mr. Byng Giraud, of Westminster, has suggested the use of an iron standard, on which the tubes might be secured, or of which they might form a part, and the lamps might then be worked up and down by means of a double rack and pinion connected by iron rods to the tiller. The standard might be fixed anywhere on the deck where it would be well in view. This would also prevent any deflection which might take place in the lines. Mr. Giraud has, however, been out with Mr. Read's apparatus in a stiff gale in the Channel, and could detect no unequal action on the lines, but they were most sensitive to every movement of the wheel. To prevent any error as to port and starboard lights, the lamps are so constructed that the port light will not fit into the tube of the starboard lamp, and vice versa. The lights as they appear and disappear in the box, or move up or down in the tubes, have the advantage of flashing lights. The lines passing from the drum of the wheel are a few seconds in their action before that of the rudder chains, so that the direction a vessel is about to take is indicated a short time before the rudder chains act. a vessel is at anchor, both the lights will be in the boxes, and the white light at the masthead alone visible. By day, an arm or sema-phore is used at the mast head with a red flag or ball for the port side, and green for the starboard.

When the collision took place between the "Bhima" and "Nada," in the Red Sea, it was a fine clear night, and the "Bhima," starboarding her helm, was endeavouring, in accordance with Art. 14 (having, we presume, the "Nada" on her starboard side), to keep out of her way. But the "Nada," having seen the "Bhima" end on, or nearly end on, ported her helm (Art. 13), but thinking the ported her helm (Art. 13), but thinking the "Bhima" was endeavouring to cross her as she would in their relative positions have the appearance of doing-suddenly changes her tactics, puts her helm hard a-starboard, and runs into the "Bhima." This, in brief, is the substance of Mr. Lacon's description of this collision, which finds its parallel in numberless cases. Had the "Bhima" known the intention of the "Nada," or had the "Nada" been aware of what the "Bhima" was doing, this terrible collision, with the loss of seventy-nine lives, could only have happened by the most sulpable neglect. We always lay by the printed record of collisions of this kind with the sad conviction of a loss that might have been prevented, and the hazy idea that somehow somebody or something must be wrong somewhere. One thing is certain—that one vessel may be ignorant of the intentions of another until the danger of collision is past recal. Nothing appears to our mind so well calculated to meet the requirements of navigation as the apparatus we have been describing, which is well received by all practical men. It has, we understand, obtained the approval of the Board of Trade and Lloyd's Committee. The President of the Liverpool Mercantile fine magic lantern transparencies produced Shadbolt, most of whom have done some-by this process. Mr. W. England, known for thing to push on their various branches of council of that body have unanimously his capital views of Switzerland, also gives an photographic science.

approved of the invention, after having made practical trials with it, both by day and night. It, therefore, only remains for the shipping interest to avail themselves of the advantages offered by Mr. Read's helm indicator, and to all interested in navigation we warmly recommend the invention.

#### IMPROVEMENTS IN PHOTOGRAPHY. No. I.

VERY good plan is adopted by the photographic journals, of printing a shilling book or "Almanac" at the end of each year, containing articles by experienced men, each of whom summarizes all that has been done during the past twelve months in his parti-cular branch of the art-science. Each com-munication is necessarily brief and to the point, and as competition induces all three photographic periodicals to bring out the best almanacthey can, these little books are of great practical value both to the experienced and inexperienced in photography. purpose to select and condense some of the most valuable information given in these annual publications, beginning with the "Almanac of the British Journal of Photography.'

This annual opens with an article by Mr. John Traill Taylor, the editor giving simple and plain instructions to beginners. The same writer also gives an article on the magic With respect to the use of common lantern. gas in the lantern, he says that although the plan is convenient, not nearly so much light can be thus obtained as from a paraffin lamp. About the best gas flame for the purpose is obtained from two fish-tail burners, one behind the other, and the gas before it reaches the burner should be well charged with some hydrocarbon, such as benzole. respect to the disputed point, whether reflectors in magic lanterns are, on the whole, advantageous, he says that they are, but that most of those in the market fail, because they are not of such a curvature as to make the reflected ray take nearly the same direction as the incident ray. A good reflector, sufficiently true for the purpose, may be made by silvering a circle cut from a blown globe of After being silvered, the reflector can be backed with tin to preserve it from injury. This plan is much better than the use of silvered copper, as the reflecting surface is more perfect, and no cleaning is ever required.

The same writer also gives an article on the coffee process, which has been rising rapidly in favour during the past few months.

The formulæ are as follows:—A large teaspoonful of roasted ground coffee of good quality is put in a teacup about two-thirds full of boiling water. After standing for about ten minutes, the infusion is filtered, and a piece of sugar about the size of a pea is added to it. This is the preservative solution. The plate is coated with rather old and red collodion, and sensitized in a somewhat acid bath. Next, it is washed thoroughly, the preservative is applied in two doses, and, lastly, the plate is dried by dark heat. A full exposure in the camera is desirable. The picture is developed by first bringing out a phantom image by the application of a two-grain solution of plain pyrogallic acid without silver or citric acid, after which the intensification is performed by the addition to the pyrogallic acid of one or two drops of a solution containing about twenty grains each of nitrate of silver and citric acid to the ounce of water. The films have a tendency in this process to slip off the glass, but this evil is averted by running a little dilute albumen round the edge of the plate before coating with collodion. By employing alkaline development, the exposure is very much reduced. We have seen some

article on the coffee process, and recommends plenty of bromide in the collodion used.

Mr. George Kemp, M.D., gives a contribution on the glycerine process, which process was first published by Mr. Valentine Blanchard, and its capabilities very fully tested by Mr. W. H. Harrison. Dr. Kemp research of the contribution of the contrib commends it for lunar and other astronomical photographs, because of the smoothness of the film, and it is also advantageous because in tropical climates it will not let the film dry rapidly, and spoil the plates, as was the case last year while photographing the eclipse of the sun in India. Dr. Kemp says that all uncertainty in the process is removed by a careful selection of pure and quite new honey. There are two varieties of new honey, one almost colourless, contained in cells beautifully white, and the other of a pale yellow or dark brown colour, from an older stock of The nearly colourless variety, he says, is the best, and secures uniformity of results with every fresh stock of preservative. Harrison has an article on the same process, recommending iron development for glycerine negatives, whenever the operator intends to copy his pictures as transparencies for the magic lantern and other purposes. Pyrogallic acid is the best, when the pictures are intended

to be printed upon paper.

Mr. Valentine Blanchard, well known for his instantaneous views of the streets of London, contributes a valuable paper upon instantaneous photography. He says that stantaneous photography. He says that scarely any of the yellow glass windows used by photographers are non-actinic enough for very rapid processes; to make the glass safe it is best to paste over it some orange tissue paper, which must afterwards be varnished to increase its transparency. The nitrate bath, strength forty grains to the ounce, must be made of the purest nitrate of silver, several times crystallized. The filtering The nitrate The filtering paper must, of course, be pure. Highly bromized collodion is necessary. The developer consists of thirty grains of photosulphate of iron, and fifteen minims of very pure acetic acid, to each ounce of water; alcohol is not necessary in the developer, because the sensitiveness of the bath rapidly falls off after a few dozen plates have been immersed in it, so that it has to be put aside for ordinary photographic work, before it is much charged with alcohol from the collodion. One very essential point in instantaneous photography is to leave the developer on the plate as long as possible, to bring out detail in the shadows.

Mr. R. J. Fowler calls attention to a new photographic paper, which will keep a very long time without spoiling before use. prepared with carbonate instead of chloride of silver, and is rendered sensitive while in the printing frame by placing pads behind it, well saturated with ammoniacal vapour. The entire success of printing depends upon excess of ammonia.

Mr. Howard Grubb, C.E., contributes a paper upon astronomical photography, with details of the method he adopted to photograph the moon with the great reflecting telescope made by himself for the Government of Australia. Mr. Warren De La Rue's reflector gave an image of the moon 14 in. in diameter, whereas the Melbourne telescope gave a lunar disc 3 in. in diameter.

The valuable little publication now under notice contains also contributions by Dr. Emerson Reynolds, Dr. Hermann Vogel, Dr. George Markham, Mr. P. Le Neve Foster, George Markham, Mr. P. Le Neve Foster, M.A.; Messrs. J. R. Johnson, A. L. Henderson, E. W. Foxlee, J. Werge, A. Pumphrey, J. Bocket, J. Homersham, G. C. Warren, M. Carcy Lea, W. Griggs, Walter Woodbury, F. Howard, Samuel Fry, E. Dunmore, R. Vevega, C. E. Pearce, E. Cocking, H. Swan, J. Beattie, F. W. Hart, Ernest Edwards, W. H. Davies, Edwards, Parent and Congression. W. H. Davies, Sylvester Parry, and George

#### RICHARDS' INDICATOR.

LTHOUGH Richards' steam engine indicator is an instrument pretty generally known, it is worth bringing prominently before our readers, not only on account of its own intrinsic merits, but in connection with a new edition of Mr. Porter's valuable treatise\* upon the subject. In preparing this new edition, the author has given considerable attention to the application of the indicator as a means of showing the degree of condensation and consequent re-evaporation in the cylinder. He has also carefully gone into the influence of the reciprocating parts of the engine upon the distribution of the pressure on the crank, and has given the method of obtaining a diagram representing this pressure correctly at every point of the stroke. Tables are given of the properties of saturated steam at temperatures from 32deg. to 213.07deg. Fah.; also of saturated steam at pressures from one pound to two hundred pounds on the square inch, and of steam at pressures of one to fourteen atmospheres. The tables of the properties of steam are compiled, as far as respects temperature, pressure, and total heat, from the memoirs of M. Regnault. The volume is illustrated by indicator diagrams in white on a black ground, and are perfect specimens of this style of illustration.

For the information of those who may yet be unacquainted with the Richards' indicator, we append the following particulars, referring our readers to the engraving of the instru-ment on page 21. This indicator has this distinguishing feature, that the throw of the piston is only one-fourth that of the pencil, while the latter still moves in a vertical line. By this means, the defects common to all other forms of this instrument, and which arise from necessity of using a long, weak, and tremulous spring, and of employing heavy reciprocating parts, which must have a considerable motion, are avoided. They have been used with complete success on locomotive engines, running at a speed as high as 260 revolutions per minute, and, indeed, it is found that there is not any practicable speed at which they will not give per-fectly correct indications. These instruments are manufactured by Messrs. Elliott Brothers, of 449, Strand, London, who make the springs to ten scales, as follows:—

No.	1.	sure or in. In	ts 1 n th	lb. ie s	q	res- uare	— <b>1</b> 5	to +	10
"	2.	-1-12th					15	,, +	22
"	3.	1-16th					15	,, +	35
"	4.	1-20th					15	,, <del>+</del>	47
"	5.	1-24th					15	÷	60
"	6.	1-30th					15	,, +	80
"	7.	1-32nd			1	\tmos	phere		100
"	8.	1-40th					٠.		125

	LO.	1-56th					•	<b>"</b> , +	

Spring No. 1 has been specially adapted to indicate the vacuum on a large scale, in engines or pumps which work at high pressures. It is important to know that all the springs will fit every instrument, and they can be readily changed by any one. The can be readily changed by any one. size of the diagram is 3 in. + 5in. drawn on metallic paper, by a pointed brass wire. The piston has an area equal to onehalf of a square inch. This is double the size usually employed, but it is the smallest that will ensure accuracy in the diagram. A special attachment, enabling the instrument to be applied to oscillating cylinders, has been arranged by the manufacturers.

ON RECENT SCIENTIFIC DIS-NOTES COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

THE EFFECT OF COLD ON METALS—A DURABLE COVERING FOR STAIRCASES—THE DENSITY OF ALLOYS OF COPPER AND TIN—SOME NEW DIS-COVERIES IN CHEMISTRY-THE ELECTRIC SEWING MACHINE.

NHE effect of extreme cold on metals, and particularly on iron, has often been remarked in this country. The axles and springs of railway carriages are known to be much more liable to fracture during a severe winter than at other times. Other metals, too, are more or less affected by cold. The leaden pipes which burst with the frost would no doubt bear a much greater strain at a higher temperature, when the metal would simply expand with the pressure. On tin, however, the effect of great cold is much more marked. Some pigs of Banca tin exposed last winter at St. Petersburgh underwent a most remarkable change. The metal became fibrous, and deep fissures were produced in various directions. Fritsche, who details the circumstances, mentions that the phenomenon had been observed before in Russia, once in the case of the pipes of a church organ which were cracked and rendered useless by the frost, a fact which shows that organs built for cold countries should be well cased. In the instance of mercury, it was stated by M. Dumas, that the frozen metal, when brought to a much lower temperature than its freezing point, undergoes a remarkable change in its mole cular state. Cold means condensation, and no doubt produces some change in the form and arrangement of the ultimate particles of the metal whereby its physical properties are considerably modified.

The wear of staircases is often a very serious matter. Whether of wood or stone, with much usage, they soon go. If of stone, the roundness of the edge soon wears away, and people miscalculate and stumble. If of wood, they are much sound down. To save them, we resort to many devices. If of wood, they are much sooner worn We cover them with lead, which, soon wearing into holes, leaves ragged edges, which catch ladies' dresses and make similar ragged edges. Or we put a thick bar of brass along thom, which sometime catch the heel of a man's boot and send him head-long down stairs. The facts being so, a really lasting and serviceable protection to staircases is a desideratum. Such a covering, M. Cazeau says he has found in thin plates of aluminium bronze. For some time, it seems, the ascent of the column in the Placo Vendôme has been interdicted to the public because of the wearing away of the stairs. It is for these that M. Cazeau proposes his covering, and if what he says is true, that the experiment has been made in a factory (it must have been a very busy one), where plates of common bronze on the stairs in thick were worn out in six weeks, while plates of aluminium bronze in thick remain just the same as when new, after eleven months of service, it is an invention which must command notice. Aluminium bronze is not too expensive if it will bear this amount of usuage; and we recommend the authorities of the Metropolitan Railway to give it a trial in place of the objectionable bars of brass to which we have alluded. Our readers will remember that aluminium bronze is merely

copper with from 8 to 10 per cent. of aluminium.
While speaking of alloys, we may mention the fact of interest to the history of these compounds mentioned by M. Riche, that the real density of the alloys of copper and tin is always greater than the alloys of copper and this always greater than the calculated density, when the proportion of copper does not exceed that required by the formula Cu<sub>3</sub> Sn<sub>5</sub>. If a larger proportion of copper than this be employed, the greatest density is observed in the case of an alloy formed of one equivalent of tin and three equivalents of copper, which is not far from the gun metal used for guns of the largest calibre.

Two or three very interesting facts in chemistry may be shortly mentioned. M. Cailletet has been studying the influence of pressure on chemical action, and, amongst other results, has found that the evolution of hydrogen by the action of water, sulphuric acid, and zinc, coases at a pressure of 170 atmospheres. Thus the disengagement of a gas under such circumstances is a phenomenon comparable to that of ebullition.

Berthelot. He placed two porcelain tubes one within the other in a furnace, which were thus exposed to the same temperature. In the outer, he placed a mixture of sulphur and carbon, and thus obtained bisulphide of carbon. Through the other but smaller tube he passed the vapour of bisulphide of carbon, and found that the two elements were dissociated or separated.

Fritsche has examined the physical properties of two solid hydrocarbons from coal tar, and finds that in the crystalline state they exhibit in an eminent degree the phenomenon of fluorescence, but once fused they entirely lose the property.

We have already mentioned the invention of a sewing machine driven by electricity. Such a machine may now be seen in actual use in Paris. The foot is now no longer needful; the "hand" has only to direct the work of the needle. The invention, although the machine can only be adapted for the lightest work, may be worthy of attention here. We do not know whether or not it is protected by a patent; but in any case the arrangement for producing the movements will be familiar to every electrician.

#### THE SMITHFIELD CLUB SHOW.

N our notice of the above exhibition in December last, we were under the necessity of directing attention to the circumstance that not only had we not been accommodated with the usual admission to the private show, but that our written applica-tion remained unnoticed, whilst the personal application of our representative was not only treated in as unceremonious a manner. We find that we were not alone, a contemporary having been treated in a similar manner. We will let the "Ironmonger' tell its own tale, which, with our own, we are sure the Royal Agricultural Society—under whose auspices the show is held-will not like to see

repeated noxt year. Says our contemporary:—

Before an exhibition is thrown open to the public, repeated next year. Says our contemporary:—

Before an exhibition is thrown open to the public, the writers for the press are invariably admitted to a "private view," in order that they may examine the objects exhibited without inconvenience. The managers of the exhibition know the value of good reports, and are usually anxious to afford journalists an opportunity of taking full notes. Unfortunately, their good intentions are occasionally frustrated by fussy Jacks-in-office who destribute the presstickets. A case in point came under our own notice in connection with the recent show of cattle and implements at the Agricultural Hall. An application for tickets to admit the editor of the "Ironmonger" and a reporter to the private view having elicited no reply, we waited on the proper officials, and reminded them of the application. We went, not as private individuals craving a favour, but as the representatives of a well-known class journal, which has become an important medium of intercommunication for the makers and vendors of agricultural implements. Had we attended as the representatives of the "Halfpenny Herald," the "Bethnal Green Democrat," or the "Petticoat-lane Scarifier," we might possibly have been welcomed as worthy members of the Fourth Estate. As it was, we were informed that there were no more press tickets, in a manner that convinced us that there was no more courtesy, or even decency, at the disposal of one of the chief officers. Next year, it is to be hoped that the directors of the Show will provide for the admission of those reporters whom the exhibitors expect to see, and take care to remind their officers that civility costs nothing.

#### HERRING'S WARMING APPARATUS.

THE object of this apparatus, illustrated in our engraving, and manufactured by Messrs. Herring and Son, of Chortsey, is to utilize a portion of the heat of waste steam in warming buildings, and at the same time to condense the steam for the boiler feed. The waste steam comes from the engine by the pipe A, passes through the coil, becomes condensed, and passes out at B. The becomes condensed, and passes out at B. The water in the cistern is thus much heated, and passing out by the pipe C, which is part of an ordinary system of hot water pipes, circulates round the building, and returns to the tank by D.

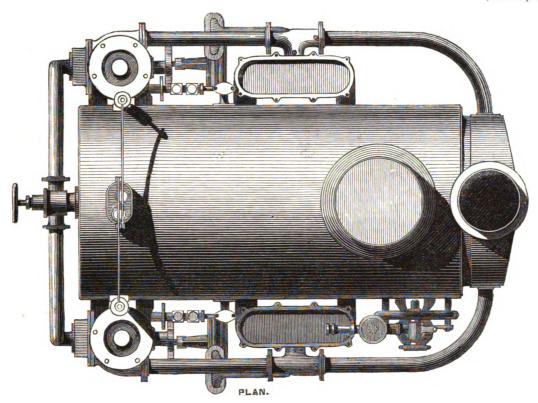

Two or three very interesting facts in chemistry may be shortly mentioned. M. Cailletet has been addying the influence of pressure on chemical etion, and, amongst other results, has found that no evolution of hydrogen by the action of water, alphuric acid, and zinc, ceases at a pressure of all will be represented and considered irrespective of the various shades of individual opinion. No pains nor expense have been spared in getting up this paper, which presents a pleasing appearance. It is conducted in an able manner, and deserves to—as it doubtless will—take a prominent position in our scientific literature. "THE ARCHITECT" is the title of a journal which

RICHARD'S INDICATOR.

INTERNAL PLAN

#### ARTILLERY EXPERIMENTS IN AMERICA

THE trial of guns against forts, commenced at Fort Monroe, was continued at Fort Delaware, on Wednesday, December 3. The target in this case was one of the casements of the fort itself, reinforced with a shield of iron. This shield was formed of two armour plates, one 8in. in thickness, and the other of 7in. The two plates were bolted together, one over the other, and supported by a framework or bracket of iron plates 2in. thick. This shield was inserted into the embrasure without being set into the masonry. It was supported by placing the brackets upholding the armour plates against piers of masonry, built in the place of the arches, connecting the casemate selected for trial with those on either side of it. These two arches had been built up solid to a depth of 8ft. from the inner face of the wall of the casemate; thus practically doubling the thickness of that wall, making it 16ft. thick, instead of 8ft. thick. THE trial of guns against forts, commenced at Fort of 8ft, thick.

of 8ft. thick.

The trial began with three shots, directed against the iron shield. The first of these shots was from a 12-inch rifled gun, with a chilled iron shot, weighing 623lb. This shot was fired with a charge of 64lb., the range in this and all other firings being assumed as 500 yards, and the charge being graduated accordingly. This 12-inch shot struck on the left of the shield, about 1ft. from the edge or the embrasure. Though the actual penetration was only 3in, the shot knocked a jagged hole, of about 1ft. square, in the edge of the embrasure, sending a piece of the inner plate, weighing some 700lb., flying into the sand-pit in the interior of the gun-room. The shot itself broke up, and a piece of it was left sticking in the shield, which was forced back some three-quarters of an inch. The piece of the inner plate, in flying back, knocked off a piece of the angle iron joining the shield to the bracket, and two bolts were broken by the shot. The second shot struck in the right-band leaves correct the shield it interest the shield it. the shield to the bracket, and two bolts were broken by the shot. The second shot struck in the right-hand lower corner of the shield. It indented the outer plate 4in., and cracked it about 6in. to the right of the centre of the ombrasure. It knocked off from the inner face of the rear plate a piece about 18in. square and 2in. thick, and broke and bent the angle-iron. The inner plate, we omitted to say, was formed of two plates, set one above the other. A crack was started in the lower of these plates, which ran to the edge of the upper. Two bolts were also broken by this shot.

The third shot struck 2ift. above the point of impact of the second shot. Its indent was 2jin.. and the plate was bent in around the shot, to the depth of 1ft. The front plate was badly cracked between the bolts, and the rear plate had a piece 18in. square knocked off of it, on the inner side in front of the shot. knocked off of it, on the inner side in front of the shot. It was also badly cracked down to the point of junction with the lower plate. The shield was forced back by these three shots directed against it, to an average distance of 3in.; the brackets were slightly loosened from the pieces supporting them; the right bracket separated from the shield and driven back 14in., and the pier of masonry at the side of the right bracket was forced back bodily lin. These last two shots were from the 15-inch gun, with 84 1-3lb. of powder. The first shot was of steel, weighing 483lb., and the second of cast iron, weighing 452lb. Six shots were subsequently fired from the same gun and with the same charge. These were 450lb. to 455lb. in weight, and were of cast iron, with the exception of the last one, which was of steel, and weighed 485lb. All of these shots were directed against the masonry on the left-hand of the embrasure. One of them struck the counterscarp, ricochetted, flew over masonry on the left-hand of the embrasure. One of them struck the counterscarp, ricochetted, flew over the edge of the outer plate of the shield, which did not cover the inner plate entirely to the top, struck the inner plate, and split it down to the embrasure, and knocked both brackets back 22in. and separated them entirely from the shield. The other shots struck fairly against the masonry, and cut it down on the outer face to an average depth of 7ft. The masonry was also knocked away over the shield, and through the opening thus made, and through the embrasure, pieces of the masonry flew into the casemate. Other pieces of the masonry were knocked off the inside of the wall, and fell into the casemate adjoining the one fired at.

adjoining the one fired at.

As a whole, however, the masonry stood better than it did at Fort Monroe. The impact of the shot was more localized in its effect, and the superior solidity of the structure was otherwise apparent. This trial, as a whole, was no more reassuring to forts and their builders than the one at Fort Monroe. Though the masonry stood better here, the ixon did not do so well, and was apparently of not so good a quality. The casemate fired at was, as in the former case, reduced to a condition which would not make it an inviting place for gunners. Some of the damage could have been prevented by the addition of an inner lining; but we do not see that this would have materially affected the result. Our engineer officers have put our existing fortifications to a severe test in these two experiments. If they had any doubts before as to their value, they can have none now.

Some of these officers, at least, are able and fair-minded men, and we have no doubt that they will be able to turn their recent experience to good account.

The problem before them is a difficult one: but The problem before them is a difficult one; but they have set themselves resolutely to work for its solution. Let them not be too closely bound by the apparent necessities of their position. These are revolutionary times, and the change in all the conditions of attack necessitates a correspondingly radical change in all the conditions of defence. There is a great reputation in store for the man who shall solve the problem of detence. Though engineer officers the world over are at work upon it, we venture our "guess" that, if the problem be solved at all, it will be by a Yankee.—U.S. "Army and Navy Journal."

#### THE WIGAN COAL TRIALS.

(Concluded from page 7.)

#### 3. PERMANENT TRIALS AND THEIR RESULTS.

VHE preliminaries just described having been determined, fifteen coals, selected by Her Majesty's inspectors of mines, Joseph Dickinson, Esq., and Peter Higson, Esq., were then submitted to trial seriatim. The following is a list of their

Hindley Yard. Worsley Top Four Feet. Upper Crumbouke. Lower Crumbouke. Upper Three Yards Six Feet Rams. Great Seven Feet. Blackrod Yard.

Pemberton Little Delf or Two Feet Mine, and Pemberton Four Feet Mine, where the two are so near together as to form one seam.

Haigh or Arley Yard.

Furnace Mine.

unnecessarv

Bickerstaffe Four Feet or Blangate Mine. Rushy Park and Little Delf Mines, worked simultaneously and mixed.

Ince Three Feet, Four Feet, and Seven Feet Mines, worked simultaneously and mixed.

Arley Mine. Although it had already been found that thick firing gave better results than thin, yet as the whole of the preliminary trials had necessarily been made with one coal for the purposes of comparison it was thought desirable to test all the coals on the list with various thicknesses of fires rather than to assume they all required precisely the same treatment, and therefore they were tried with fires 9in. thick, and then with 12in. thick, the latter being thought at first the greatest thickness permissible, but experience showing that 14in. fires could be managed, additional samples of the coals, where necessary, were procured, and further trials made with 14in fires. Added to this, a longer trial was made, in which 1,500lb. of coal was burnt instead of 1,000lb., as in others, in order to see how far the coal would maintain its efficiency in a long run. Also the effect was tried of closing the perforations in the firedoors as an indication whether too much air has been admitted or not. In all the trials just named the "coking" system of firing was adopted, but an additional one with "spreading" firing 12in. thick was made as a comparison, and as it was found in all cases that coking firing proved to be the most economical, further trials on the spreading system were thought

The result of these trials showed that the coals possessed a very high evaporative power combined with great speed; one coal evaporating 11:101b. of water, at 100deg. per lb. of coal; a second, 11·15lb.; a third, 10·49lb.; a fourth, 10·91lb., &c., &c.; while in the case of the first, 46·17 cubic feet of water were evaporated by the boiler per hour; in the second, 48·60 cubic feet; in the third, 51·34 cubic feet; in the fourth, 45·37 cubic feet; while only a little faint smoke was occasionally visible. These results were very superior to those reported to the Admiralty in 1849 by Sir Henry De La Beche and Dr. Lyon Playfair, who returned the economic evaporating power of the best of the Lancashire coals as only equal to 8lb. of water at 100deg. evaporated by 1lb. of coal. The results obtained from the South Lancashire and Cheshire coals were found to compare very favourably with those water, at 100deg. per lb. of coal; a second, 11.151b.; were found to compare very favourably with those obtained from the North Country and Welsh coals at Her Majesty's dockyard, Keyham, but it was thought it would be of further satisfaction to, try the Welsh and Newcastle coals in the Wigan boiler for comparison and this was therefore does. for comparison, and this was therefore done. results will be more readily seen if arranged in the form of a table, as follows:-

٠						

Detailed results of the permanent trials of the whole series of coals, when treated on the coking system, with the fires 14in. thick, and the perforations in the doors intermittently open-which were the conditions that afforded the highest resultswill be found in the tables appended; but as the detailed tables c. the remaining trials—made under various conditions as to the thickness and treatment of fires, admixture of air with the gases, and length of experiment—occupy as many as thirty-eight sheets, it was found impracticable to include them in extenso in this report, but the condensed results are subsequently given.

When all the coals on the list had been tested, When all the coals on the list had been tested, and the results given in the tables just referred to arrived at, the Admiralty sent down two of their officers, Robert Nicoll, Esq., R.N.. Assistant to Chief Engineer at Her Majesty's dockyard, Keyham, and William Lynn, Esq., Assistant Inspector of Machinery at Her Majesty's dockyard, Portsmouth, to witness a repetition of the trials and report thereon. report thereon. A table giving the results obtained by the Admiralty officers will be found on sheet No. 2. All the trials hitherto referred to were made with the natural chimney draught, but it was thought well for the Admiralty officers to witness a second series with the draught quickened by mechanical means, and therefore a steam jet fed by an adjoining boiler at a pressure of 30lb. per square inch was applied to the chimney. A table giving the results of this second series of trials by the Admiralty officers will be found on sheet No. 2a.

To facilitate a comparison between the results of the original series of trials and of the verifica-tions by the Admiralty officers, sheet No. 3 has been prepared, which gives in parallel columns the net results of the different trials of each of the coals on the list, while the following table gives the mean of the whole:-

tried by Admiralty officers	10-18	69-13	41	0.0		

<sup>\*</sup> See MECHANICS' MAGAZINE for December 18, 1868, page 487.

This table shows that the Admiralty officers more than verified the results previously given, and in reporting to the Admiralty thereon they stated that such is the case.\*

Further to test the value of the coal, it was thought well to have a trial at sea, and therefore a run was made with the "Lindsay," a screw collier of 800 tons burden, fitted with two boilers, each containing three furnaces and driving a pair of engines having a diameter of 28in. in the cylinder, making 701 revolutions per minute and indicating about 460-horse power. The trial was most satisfactory; coking firing, as already explained, was adopted and carried out by the ordinary ship's stokers, and Messrs. Nicoll and Lynn report that steam "was kept blowing off at the waste steam pipe all the time of the trial, while no smoke was visible during the whole of the four hours' run."† The commissioners close their report with the following words:—"In conclusion, these experiments, including that of the 'Lindsay,' show that when the products of the coal are consumed, which we consider can be easily done by careful firing, the coals of this district have a high evaporative value, combined with great speed, and are in every respect fit for Her Majesty's Service.

To assist in estimating the advantages of different thicknesses of firing, sheet No. 4 has been prepared, which gives the results of firing each coal with a thickness of 14in., 12in., and 9in. The following table gives the mean results of the whole number of coals at each thickness of fire:—

COMPARATIVE TRIAL OF THE RESULTS OF DIF-FERENT THICKNESSES OF FIRES.

	deg	r at per	per of	Smoke p.hour			
CHARACTER OF TRIAL.	Lbs. of Water at 100 evaporated per lb. coal.	Cubic Feet of Water 100deg. evaporated 1 hour.	Lbs. of Coal burnt hour per square foot fregrate.	Minutes of Very Light.	Minutes of Brown.	Minutes of Black.	
Mean Results of all the Coals, with Coking Firing. Fires 14in. thick	10-35 10-06 9-65	47·22 45·67 44·00	27 27 27	2·4 2·8 1·0	:::		

From this it will be seen that a fire 14in. thick gives a more economical result than one 12in. or 9in. thick, while no diminution of speed is experienced. To show that "coking" firing coupled with the admission of a little air above the bars immediately after charging, which is the smokeless system, is not attended with any loss in economy, sheet No. 5 has been prepared, which gives the result of three different systems of treatment applied to each coal:-1. The coking system coupled with the admission of sufficient air above the bars to prevent smoke. 2. The "coking" system with perforations in the fire-door closed; and 3. The "spreading" system with the perforations in the firedoor after charging.

The following is the mean result of each of the three systems :-

COMPARATIVE TABLE OF THE RESULT OF FIRING ON THE COKING AND ON THE SPREADING PRIN-CIPLE, AND ALSO OF ADMITTING AIR AT THE FIREDOOR OR NOT.

	og.	r at per	per of	Smo	ke p.	hou

door open after	9:51	51.37	32	20.8	5.3	4.2

See Paragraph 12 in report of Messrs. Nicoll and Lynn to the Admiralty on the steam coals of South Lanca-bhire and Classhire, dated 1867.
 See Paragraph 17 Messrs. Nicoll and Lynn's report.

A consultation of this table will show that there is no loss in economy from adopting the smoke-less system of firing, but, on the contrary, a slight though there is a loss of speed, neither as much coal being burnt per square foot of fire-grate nor as much water evaporated per hour from the boiler. Thus the table shows at once the advantage and difficulty of smoke prevention. experienced It is feared that difficulty will be wherever boilers are overtasked, while it will be seen that the table affords an explanation of the objection entertained by firemen to admitting air above the firebars when they want to raise steam quickly.

On making a longer trial, that is to say, consuming 1,500lb. of coal instead of 1,000lb., and running for an average length of time of 5hr. 9min., instead of 3hr. 27min., the result was slightly inferior in economy, though practically equal as regards the amount of water evaporated by the boiler per hour and the absence of smoke. The precise figures are given in the following

COMPARATIVE TABLE OF THE RESULT OF SHORT AND LONG TRIALS.

-	trial.	con-	100deg. lb. of	per per	per of	Smok	e p.h	our
CHARACTER OF TRIAL.	Average length of tri	Amount of Coal c sumed.	Lbs. of water at 100c evaporated per 1b. coal.	Cubic feet of water 100deg. evaporated hour.	Lbs. of coals burnt hour per square foot firegrate.	Minutes of Very Light.	Minutes of Brown.	Minutes of Black.
Short trial	h.m. 3-27	1,000	10-29	46.81	27	2.4		
Long trial	5-9	1,500	9.76	45:71	28	2.0		

It may be added that in this series of trials the fires were treated on the coking system, as before, and that in some cases they were 14in thick, in others 12in., and in one 9in.—care, however, being taken, in queting the result of each coal, that the thickness of fire should be the same in the short trials as in the long, so that the comparison is a correct one,

Such is a very brief account of the series of trials of the South Lancashire and Cheshire coals. will be seen, however, that these coals have a high evaporative value combined with great speed, some of them as returned by the Admiralty officerswho were sent down to investigate and reportbeing able to evaporate 11.3lb. of water at a temperature of 100deg. per lb. of fuel at a speed of 26lb. of coals consumed, and 4·7 cubic feet of water evaporated per square foot of firegrate per hour, while the mean of the fifteen coals tried, gives an evaporation of 10.68lb. of water at 100deg. per lb. of fuel at a speed of 27lb. of coal burnt and 4.6 cubic feet of water evaporated per square foot of firegrate per hour.

Since these trials, as previously stated, had special reference to the suitability of the South Lancashire and Cheshire coals for use in Her Majesty's Navy. round coal was used almost entirely, and not slack. These trials, therefore, do not exhaust the whole subject of the economy of fuel with regard to mill purposes, yet it is thought there are several points in them which are of general interest, and that the circulation of information with regard to them will prove of assistance to the ordinary steam user. It is of interest to note that the free burning and gaseous coals of this district were burnt in these trials with the entire absence any smoke beyond the faintest trace, and that this was accomplished both at sea and on land, and that, not by means of any special apparatus, but simply by careful firing, accompanied by the admission of a little air through the firedoor, for a short time after charging. It should also be noted that economy was the result of this smokeless system of firing, and of the admission of air through the firedoor; also that thick fires were found to be more economical than thin, and short firegrates than long ones, and though due regard must be had to the amount of steam required, yet it is thought the nreguests mill boilers are, as a rule, too long.

L. E. FLETCHER. yet it is thought the firegrates in ordinary use in

A series of valuable sheets of tabulated results are appended to Mr. Fletcher's report, but for which we are unable to find space.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE sixteenth annual meeting of members took place on Saturday, the 2nd inst. It was ex-

ceedingly well attended, and the chair was occupied by Mr. J. Newton. moment consisted in the The first business of presentation of balance sheet of the last half year, and the report thereupon of the auditors—Messrs. Irvine and Bulleugh. From these documents we gather that the Association, in spite of the continued depression of trade, is in a satisfactory condition, numerically and financially. The number of ordinary members and financially. is 104, and of honorary members 64—total, 168. The general fund, invested or in hand, amounts to £429 2s. 11d., and the superannuation fund the interest upon which only is available for the partial support of decayed foremen—equals £903 18s. The fund for the solace of widows and orphans is very minute, amounting to £10 only. It is subscribed to homeopathically, to all appearance, by ordinary members solely. During the past year, £103 were paid to unemployed associates, and £33 as solatia to the families of those who died in the same period.

The balance sheet and report were, after some discussion, unanimously accepted. Mr. Briggs having explained the nature and agreeable results of his visit to the Leeds Association of Foremen, which, too, is in a thriving condition, Mr. Newton proceeded to deliver the president's annual address. This was of considerable length, and of much interest, but it is not possible for us at present to give it in extenso. After alluding to the gratifying fact that the Institution is steadily progressing and gaining more and more the countenance and support of employers, Mr. Newton furnished biographical sketches of Messrs. Tomlinson and Clark, two associates, whose deaths occurred in 1868. Mr. Tomlinson was foroman of boiler makers at the Royal Dockyard, Woolwich, and Mr. Clark, foreman of moulders to Messrs. Maudslay, Sons, and Field. Details were given of their professional careers, of their personal characteristics, and of their scientific acquirements. It was (observed the president) a matter of regret that the materials for these biographies were scanty, although it was known that both associates had passed through many vicissitudes. "Were we one and all to keep diaries, and make careful note of our labours, our cares, our hopes, our fears, our disappointments, and of our triumphs over difficulties, what interesting and valuable memoirs might not be written by kindly hands of the foremen engineers?

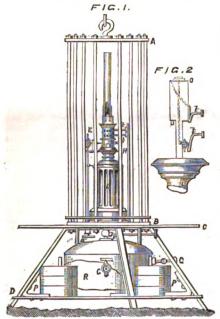

Turning next to the Association itself, the president reviewed its proceedings in the past, and indicated what he considered should be its course in the future. The early efforts made for its establishment had been well sustained by its founders, and the Institution was at that moment healthy and vigorous. Energy and activity, however, on the part of every member were essential ever, on the part of every memory more for the promotion of its future prosperity. Apathy was the evil to be contended against—the palad which must be removed. "Let but rock ahead which must be removed. "Let but the intellectual strength and the practical know-ledge of the associated foremen be put forth and developed in the lecture room as they were in the factory, and their society would take a high place in the estimation of scientific men of every grade. From a knowledge of the materials of which the Association is composed, I am inclined," said Mr. Newton, "to predict that a day will come when the affixing of the initials F.E., as constituting membership, will entitle those who use them to an amount of consideration second only to that accorded to the C.E. and the M.E. It rests with members themselves to achieve this elevated position for the Association.'

The necessity of increasing largely the facilities for technically instructing youth intended for the workshop was dwelt upon with much emphasis, and at considerable length, and Mr. Newton concluded his remarks by thanking members generally for the uniform kindness he had experienced on all occasions at their hands. His tenth year of office had now expired, and, as an old hand, he trusted he might retire into private life with a "fair" certificate. Retirement, however, was not allowed to the president on this occasion, for Mr. Newton was at once re-elected to the office on the motion of Messrs. Hosken and Keyte, the two oldest mem-Mr. Keyte was re-chosen as vice-president; Messrs. J. Irvine, Cutler, and Dewer were appointed members of the Committee; and Mr. Edmonds, of Woolwich Arsenal, was elected as auditor for the ensuing half year. With a vote of thanks to Mr. Newton for his address, the business of the evening came to a close.

We have since learnt, with much satisfaction, that Joshua Field, Esq., C.E., has consented to preside at the anniversary banquet of the Association on February 20.

#### SUBMARINE LAMP.

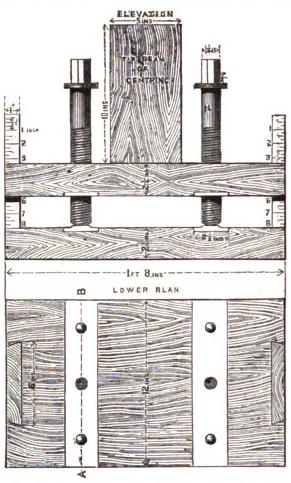

THAT, in some instances of explosions in mines, the safety lamp has not been a protection in times of danger, there is abundance of evidence to testify. We do not allude to cases where the lamp was opened or otherwise tampered with by the miners themselves, but to those where, in fact, the lamp failed to discharge its own duty. Not only in mines are other than the ordinary means of illumination required, but also in those situations where engineering and constructive works are carried on by night under water. Hitherto, the submarine lamps employed may be ranked under two separate classes—those which are oil and those which are electric lamps. The first of these were fed with the necessary quantity of air, by means of long india-rubber tubes connected with pumps, of long india-rubber tubes connected with pumps, and required a constant expenditure of manual labour to keep them alight. Moreover, the light was very poor and dim, and the tubes were incessantly in the way of the divers engaged in the work. The electric lamp had one difficulty to contend with, and that was its high price. There was also another circumstance attending its use, which resulted from the actual brillians of the which resulted from the actual brilliancy of the light it threw out. It was the intensity of the shadows. It is well known that the more brilliant the light the deeper the shadow, and so deep have the shadows of the electric light proved that they have been acknowledged to seriously interfere with the utility of that vivid source of illumina-tion. Aware of the many inconveniences in cornection with the existing lamps, MM. Leanté and Dénoyel, two former pupils of L'Ecole Polytechnique, proposed to construct a lamp which should carry its own source of illumination, burn without any communication with the external air, and be less expensive than its predecessors. This lamp is represented in fig. 1, and we shall briefly de-

scribe it.\* We may previously remark that it has been tested with the most satisfactory results in the presence of the members of L'Académie des Sciences.

The lamp belongs essentially to what is well known as the moderator type, which were so much in vogue previously to the introduction of their simpler rivals and supplanters—the paraffin lamps. The gas which feeds the lamp is oxygen, and compressed by ten atmospheres, is enclosed in a reservoir placed below the lamp, and is conveyed by means of a small tube to a pair of annular receptacles, one of which is outside and the other inside the wick. Both of these are pierced with a number of the below. the wick. Both of these are pierced with a number of small holes. There are simple appliances for regulating the motion of the wick and the supply of the gas. A thick glass cover protects the lamp from external influences. Two principal conditions have to be fulfilled by a light of this description. It must, in the first place, carry its own supply, and, in the second, provide for the results of combustion. The former condition may be comparatively easy to fulfil, but the latter is surrounded with many and serious difficulties. Precautions must be adopted to prevent the products of combustion accumulating in the vicinity of the wick,

#### EDWARDS' LAUNCHING BOX.

and interfering with the illuminating properties of the flame. The problem to be solved was, in of the flame. The problem to be solved was, in reality, that of constructing a lamp which should consume its own smoke. After the inventors had lighted the lamp, and enclosed it in its case of crystal, it was observed to continue burning without any intermission or diminution of brilliancy, and upon searching for the products of combustion it was discovered that they took the form of a condensed liquid, which was diffused over the sides of the glass cover. In order to explain the principle of this curious phenomenon, it must be assumed that the products of combustion in their nascent state, being brought into contact with pure oxygen, constitute by combination with that gas a liquid compound resembling the oxides or carbides of hydrogen.

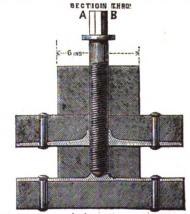

Referring to fig. 1, the lamp is represented in full elevation, and in fig. 2 is shown to a larger scale, a portion including the wick. The lamp L is placed in the interior of a strong glass cover, closed at its two ends by the two brass discs A and B, solidly joined together by the long bolts shown in the engraving. The lower disc B is attached to a guide plate C, connected to a lower one D by the iron pieces represented in fig. 1, the whole forming a sort of tripod upon which the apparatus rests when lowered to the bottom of a river or sea. Two heavy weights PP, are placed upon the tripod frame to counteract the upward tendency of the frame to counteract the upward tendency of the water. Between the upper and lower guide plates C and D is situated the reservoir R, containing the supply of compressed gas. The wick is supplied with this gas or fed by opening the cock F, which causes it to enter the tube H, and thence to pass into the smaller tubes t t; the first of these conducts the gas to the outside of the wick O (see fig. 2), and the other to the inside. To regulate the height of the wick, all that is required is to turn the milled headed screw E, which is connected by means of a vertical rod with an endless scrow, gearing into the small bevel wheel E. This latter acts directly upon the axis carrying the wick and moves it up or down, as may be requisite. In addition to these mechanical details, the reservoir R is furnished with a couple of cocks G and G. One of these serves for the filling of the reservoir, and the other is for the purpose of receiving a metallic gauge, for registering the amount of the pressure. Experiments have fully confirmed the

anticipations formed of this submarine plan of illumination. The flame is pure, brilliant, and regular, and remains constant in these particulars without any necessity for altering the height of the wick for a period of three-quarters of an hour. By increasing the pressure of the gas, and the size of the reservoir, it is expected that the duration of the constancy of the flame will be considerably prolonged.

This lamp, such as it is, or with whatever trifling modifications further experience may indicate to be advisable, appears to solve the problem of illuminating other media than that of the atmosphere in a very satisfactory manner. In the numerous instances where it is necessary to lay foundations under water, it will be found a valuable assistance to the diver, and it is well calculated, from its flame being altogether severed from all communication with the external air, to prove an effective source of illumination in mines, where the firedamp and explosions claim annually a certain number of victims.

## EDWARDS' LAUNCHING BOX.

WE recently described the hydrostatic sluice gate, designed by Mr. W. Edwards, C.E., of 52, Gracechurch-street. We now illustrate another

Digitized by Google

<sup>\*</sup> We extract the cut and the explanation from our valuable contemporary, "Le Genie Industriel."

nious form of launching box, for lowering the centreing of bridges. This appears to be a very simple, cheap, and safe invention for this purpose; one man with a spanner in each hand being sufficient to lower the centres of a 60ft. span bridge in fifteen minutes without any risk. Its construction is rendered so clear by means of the illustration, that any further description is unnecessary. This launching box was used successfully in launching a bridge on a skew of 44ft. or 56ft. with the centre line of roadway in fifteen minutes, with one man and one coolie, and the deflection of the crown of the arch was only one-thousandth part of a foot, as nearly as could be observed by a powerful instrument. The bridge referred to was across the South Channel Sreeramdavur Dam, Talook, Mysore; and span 41ft. Gin. on the square, easily transported, weighing only 32lb. each, for a 40ft. span, and can be fixed in any position for launching. The scales mark exactly the degree to which the centre beam has been lowered. The cost of the apparatus is, we believe, very small.

#### IMPROVED LEVER WATCH CONSTRUC-TION.

THE annexed engravings represent an improved method of constructing lever watches according to the patented invention of Mr. Borthwick Smith, of Coventry. The improvements consist in the adaptation of the detached lever and other escapements to watch movements constructed upon the 3-plate principle, but in such manner as facilitate the complete separate detachment of the escapement, without displacing any other part. At the same time, it affords the same freedom for action as in full-plate watches, instead of cramping the pallets and pallet-wheel under a cock beneath the balance, as in the usual \(\frac{3}{4}\)-plate construction. In the patent movement both this cock and the escapement bar on the pillar plate are dispensed with, and the escapement is pivoted into the solid pillar plate and a bar on the top plate, by removal of which latter the pallets and pallet-wheel are detached.

The patent lever escapement, as adapted for this construction, is pitched with the pallets at right angles to the lever, and having their centre of motion in a straight line from the balance staff to the pallet-wheel hole. The roller and pallets are constructed in the usual manner, except that the diameter of the former and the size and draught of the latter are so proportioned as to compensate for the increased length of lever, and give the same action as in the ordinary detached lever escape-The lever is extended beyond the front of ment. the pallets under the pallet-wheel, in order to balance it fore and aft of the pallet staff. The arrangement of the train of wheels, the hollow centre pinion for setting the hands from the back, fusee compensation, maintaining power, stopwork, &c., is the same as in the ordinary 3-plate move-ment, but the frame is constructed in different ways to adapt it for the different fashions of watch case. For instance, construction No. 1 (shown in

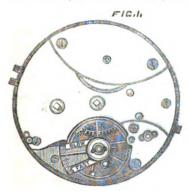

fig. 1), for consular cases, has the escapement bar fixed at the extremity of and beyond the top plate, to which at the one end it is screwed, and at the other end, beyond the escapement, it is screwed to an extra pillar, placed opposite the balance. bar is also fixed on the top plate to receive the barrel (as in full-plates), and allow of its separate detachment when necessary.

Construction No. 2 is specially adapted for being

fully capped and fitted in consular cases, and has arrangement as No. 1 for separate detachment of the barrel and escapement, but the escapement bar is screwed to the top plate only, over a hollow filed in the plate round the pallet staff and pallet-wheel holes, while the balance cock being at the aft extremity. The barrel of the

is also dispensed with, and replaced by a bar on the top plate planted alongside the escape bar. This arrangement (with the balance under the top plate and the pendulum spring working in a small hollow round the staff hole) admits of being fully capped at small additional cost. A novel mode of indexing and regulating this construction is also adopted. Construction No. 3 (shown in fig. 2),

specially adapted for dome cases, has the escape bar fixed in the same manner as No. 1, but the top plate is made rather thicker, and the bar, instead of being screwed on the top of the plate, is countersunk on the edge of it; the barrel bar is also dispensed with, and by this means the top plate is made all-flush on the top, as required for domecased work

Construction No. 4 has the top plate made the same as either No. 1 or No. 3, but into the escape bar is pivoted either the pallet-wheel only, or the fourth and pallet-wheels, while the pallet staff is pivoted into a small cock beneath the balance, and the pallets set for action in the same manner as above described, but with the shortened lever. Neither construction adds to the thickness of the watch to any extent, as compared with ordinary \(\frac{3}{4}\)-plate watches. The pendulum stud is so fixed that the removal of the balance staff does not necessitate the unpinning of the pendulum spring or alteration of the regulator. Besides the important point that (on account of the simplified construction, and consequently reduced cost of finishing lever watches upon this principle) the manufacturers—Messrs. John Ryley of 17, Hertford-place, Coventry-are enabled to supply sound and accurate timekeepers, having all the advantages of 4-plate work, at a much lower price.

The other advantages of this invention are manifold, and may be summed up as follows:— The facility afforded for separate detachment the escapement, for cleaning or repairs. The increased amount of freedom and stealier action imparted to the escapement, consequent on the increased length of the arbors. Less liability to stop or perform irregularly, from oil thickening or dust accumulating, on account of the escape-ment having more freedom. Then there is the ment having more freedom. Then there is the facility for setting the hands from the back, and also that afforded for separate detachment of the barrel to fit in a new main spring when broken, or for other purposes. There is also an increased depth of main spring, which admits of the use of a spring of smaller force and steadier action, give the same amount of impulse to the train. barrel bar is readily removed (as in full plates) to engrave the name of the vendor on it, without taking the watch to pieces. Finally, we have the facility (construction No. 2) for fully capping and covering up all the working parts of the small cost, and the reduced liability of the main spring and chain to breakage, on account of the We underweaker force of main spring required. stand that these watches are coming into extensive use in the North of England, and are found to answer remarkably well.

#### HIGH PRESSURE STEAM LAUNCH WITH SURFACE CONDENSERS.

WE illustrate at pp. and an arrangement of engines and boilers for one of her Majesty's steam launches, constructed by Messrs. J. and G. Rennie. One of the principal features in this design is, that although the steam in the boiler is raised to 80lb. on the square inch, surface condensers are used for the first time, we believe, in engines of this class. The side elevation shows

shell is 2ft. 5in. in diameter, and the length is 4ft.  $9\frac{1}{2}$ in.; the number of tubes forty, the outside diameter of each being  $1\frac{3}{4}$ in., and the length 3ft. The firegate is 2ft. wide and 2ft. 5 in. long. The products of combustion escape through a chimney 9in. in diameter. The boiler is fitted with a steam dome 13in. in diameter and the same height from the shell. The smokebox is at the stoking end of the boiler. The safety valves are the ordinary spring and lever kind, with a raised provision secured to the shell of the boiler at the aft end. The end elevation shows the gauge glass, cocks, surface and bottom blow-out valves. engines are direct acting, with double guides, which act also as stays; only one cylinder is employed to drive each screw shaft, contrary to arrangements by other firms, where two are introduced. Each cylinder, in the present case, is 6in. in diameter, and the stroke for the piston

6in. The diameter of the piston rod is 1in.

The crank shaft, 1\frac{3}{4}in. in diameter, is supported in bearings 2\frac{1}{2}in. long, secured under the base of the boiler. The forward extremity of the shaft transmits motion, by spur gearing, to the centrifugal pump, which circulates the sea water through the condenser, seen in elevation and plan. The surface condenser can be converted into the injection system by the pipe in connection with the top and bottom portions, seen in the side elevation. The condensers contain eighty-six tubes, each being 9-16in, in diameter. The steam passes from the cylinder to the top portion of the condenser above the tubes, and is drained by the feed or above the tubes, and is drained by the feed of donkey pump as may be required. The latter pump is  $1\frac{1}{4}$  in in diameter, having a stroke of 3in., the feed pumps being  $\frac{7}{3}$  in in diameter, with a stroke of 6in., receiving their motion from the crossheads, as shown in the end elevation. Both donkey and feed pumps are fitted with non-return valves attached to the boilers. The link motion for starting, stopping, and reversing the engines is simply arranged. The end elevation shows the is simply arranged. The end elevation shows the motion very clearly. A single lever only is required, and the stationary point is maintained by a rod and set screw to each motion. The arrangement of the steam pipes is so obvious from an inspection of the engravings that a description is

unnecessary.

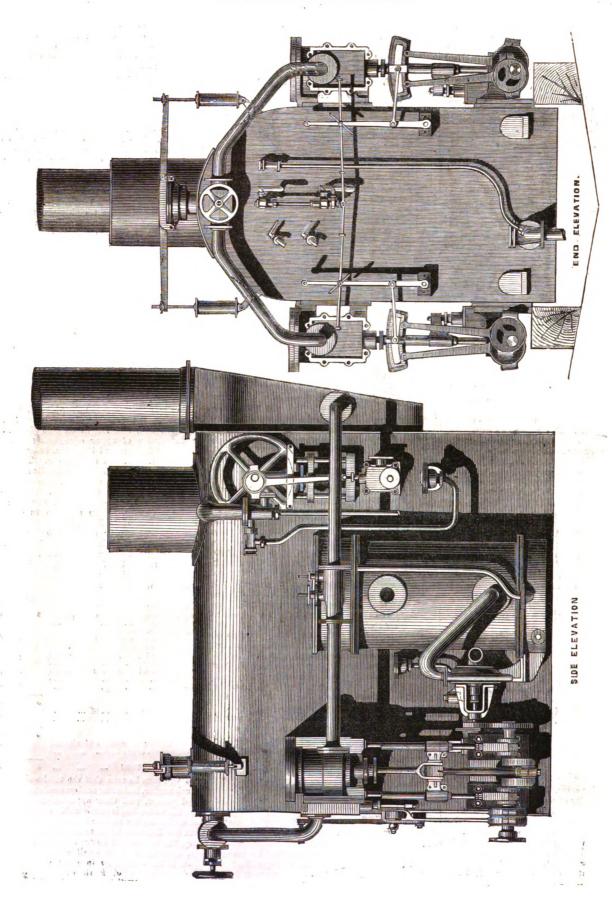

The screw propellers are four-bladed, right and left-handed, the diameter of each being 2ft. 6in., pitch 3ft. 6in., and length on line of keel  $3\frac{1}{4}$ in., the immersion of upper edge being 3in. The launch is 42ft. long and 10ft. 11in. beam; draught forward, 1ft. 11in., and aft, 3ft. ½in. The trial of these engines gave the following results :- Number of revolutions of engine mean, non-condensing, 326:333; with condenser, 328:5. Pressure of steam in boiler, non-condensing, 80:83lb.; with condenser, 73:25lb. Mean pressure in cylinders, non-condensing, 54:958lb.; with condenser 58:344lb. Indicated horse-power (nominal 5 horses) non-condensing, 30-732; with condenser, 32-84. Mean speed of launch, non-condensing, with and against tide, six runs, 7.897 knots per hour; with condenser, under similar circumstances, 8.054 knots per hour. We append the weights of material.

T T	ons.	cwt.	qrs.	lb.
Engines, boiler, centrifugal pumps, sur- face condensers, donkey engine, &c., as lifted out	2	6	0	0
Stern tube, propellers, shafts, stern brackets, propeller shafts, thrust bear- ings, bolts, and holding down plates		8	0	0
Sea cocks and pipes, discharge roses, bolts and nuts		1	3	0
Coal boxes and spanner racks and		3	0	0
spanners		2	0	0
	3	0	3	0
Water in boilers Do. in condensers		7	3	0
	3	8	3	0
Engine bearers of wood, and chocks forming part of the boat		4	2	0
Total	3	13	1	0

It will thus be seen that the total weight of the launch engine, including surface condensers, centrifigal pumps, and their appurtenances, together with the water, &c., is considerably under four tons; and excluding the surface condenser and its pipes, as in the launches hitherto adopted in the English navy, the weight will be 8cwt. less, or 3 tons 5cwt. 1qr. altogether. This small additional weight of Sewt. is the substitute in these engines for the cumbrous tanks of fresh water placed in the ordinary launch, the weight of which, with the water in them, is upwards of a ton. There is, therefore, a clear gain in the engines of this launch of about 12cwt. over those previously adopted, with a gain in speed and in space occupied in the length of the vessel.

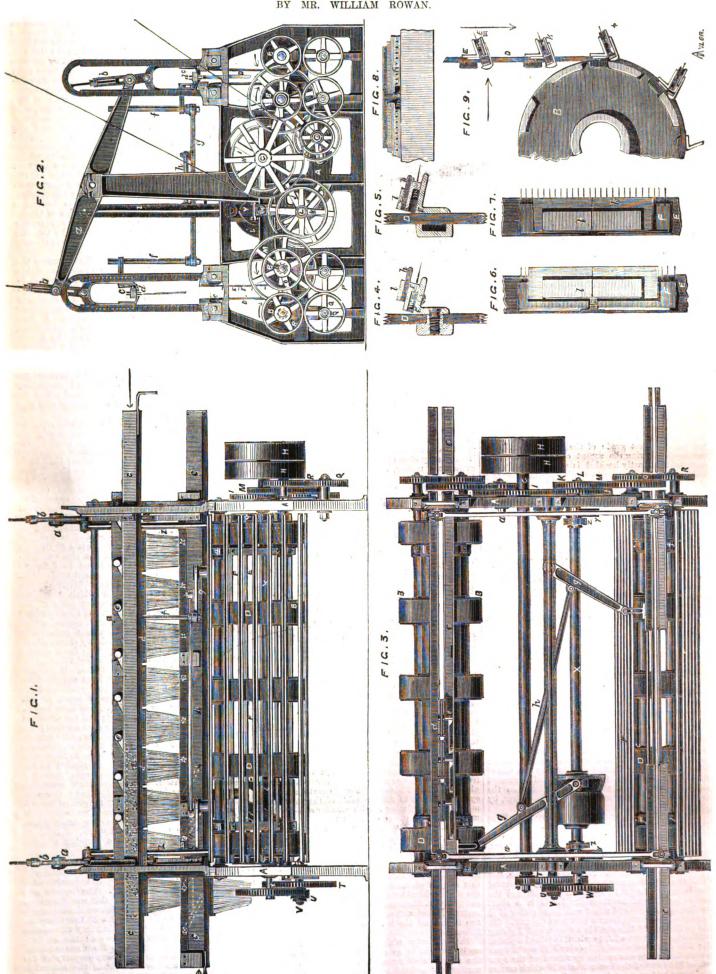

# HIGH PRESSURE STEAM LAUNCH WITH SURFACE; CONDENSERS.

BY MESSRS. J. AND G. RENNIE.

## HACKLING MACHINERY.

BY MR. WILLIAM ROWAN.

#### HACKLING MACHINERY.

MR. WILLIAM ROWAN, of the firm of John Rowan and Sons, of Belfast, has recently patented some improved machinery for hackling flax, hemp, &c., and which we illustrate on page 27. The invention possesses three features of novelty. It consists, firstly, in a new mode of fixing the hackle pins to the stocks and bars, and of attaching them to endless belts or sheets passing over drums placed one above the other, so that the hackle pins shall act upon the fibre at an angle of from 70deg, to 80deg. Secondly, in an arrangement of movable bars, termed stripping bars, which are for the purpose of freeing the hackles from the tow after they have operated oa the fibre, thus abolishing the use of brushes, card drums, and doffing combs, together with the costly arrangements necescombs, together with the costly arrangements necessary for their connection to the machine, and their mechanism of working. In the third place, it consary for their connection to the machine, and their mechanism of working. In the third place, it consists in applying guide bars to the upper and lower shafts which carry the drums, around which the belts for carrying the hackle bars are placed. The object of these guides is to cause the hackle bars and hackles to move in a parallel line, so that the tension or rigidity of the belts is not depended upon alone.

The machine itself consists of two end frames between which, on each side, a series of drums is placed one above the other, around which pass end-less belts, to which hackle bars are attached, these drums and belts being so placed that the flax during the period of hackling shall be operated upon both the period of hackling shall be operated upon both sides at once. Upon a shaft extending across the machine is placed a heart-shaped cam, which gives a reciprocating motion by means of a connecting rod to a rocking beam, which in turn imparts an ascending and descending motion to two galleries placed in guides, one on each side of the machine, and connected to the rocking beam by variating links; at the commencement of the hackling, the pitch of the hackles is somewhat far apart, but gradually becomes narrower towards the opposite end of the machine.

The action is as follows:—The stricks of flax in proper quantities are firmly fixed in holders and placed in one end of the galleries, so that the tails hang between the belts or sheets, and on the descent of the galleries are brought in contact with the

hang between the belts or sheets, and on the descent of the galleries are brought in contact with the hackles of the first or widest pitch, and the downward motion of the flax being continued through the hackles, the first grade of the hackling action is produced. During the ascent of the galleries, the material thus partly hackled is propelled with the holder a certain distance to another position between the hackles, the pitch of which, as previously ex-plained, being progressively narrower, the flax is subjected to a finer grade of hackling and so on, until it has been propelled the whole length of the row of hackles, by which time the hackling of one end is finished.

One attendant on the machine supplies holders charged with flax as space is left by the preceding holders having advanced on their journey across the machine, and on the arrival of each holder at the machine, and on the arrival of each holder at the opposite end, another attendant receives it, and after reversing the flax, end for end, in the holder, he passes it along the other side of the machine, to be subjected to a similar operation on that portion of the material proviously in the grasp of the holder, and consequently untouched in the first stage of operation. Thus, since both sides of the machine are precisely similar, when the holders have made their return journey and arrived at the end they started from the flax contained in them is comstarted from, the flax contained in them is com-pletely backled throughout the whole length of the fibre, and the first-named attendant removes it in a finished state, making use of the holders for fresh portions of flax; the progressive motion of the holders continues across the machine as long as fresh ones are supplied.

continues across the machine as long as fresh ones are supplied.

The propelling motion of the holders is accomplished by means of pawls connected to slides on the top of the galleries, which slides are moved by means of two levers and upright bars, the levers being connected together by a connecting rod, one of the levers receiving the forward and backward motion from a grooved pulley or wiper fixed on the cam shaft, and giving motion to the other lever, by means of the connecting rod just referred to.

In our engraving, fig. 1: as side elevation of the machine; fig. 2, an end view; and fig. 3, a ground plan. Figs. 4, 5, 6, 7, and 8 are different views of the hackle bars, stocks, and stripping bars, drawn on a larger scale. A A are frames of cast iron, one at each end of the machine, connected together by cross stays. B B are the lower, and C O the upper drums, around which are passed the belts or sheets D, to which are attached the hackle bars E and hackle stocks F. G is a shaft having on it at one end a fast and loose pulley H H to receive the motion from a belt from the Ill. On to receive the motion from a belt from the mill. to receive the motion from a belt from the mill. On the pulley end of this shaft is a spur wheel I giving motion to a spur wheel J, to which is joined a pinion K; this combined wheel and pinion J K works upon a stud L, and imparts motion by means of the spur wheel M to one of the lower shafts N which carries the lower belt or sheet drums B. On this same shaft is another spur wheel O gearing into a wheel P fixed on a stud below. This wheel P gears into a similar

wheel Q, also fixed on a stud, and this gearing into another wheel R above it, gives motion to the other lower drum shaft, the upper drums C receiving their motion from the lower drums B by means of the belts or sheets D. Both sides of the machine being arranged in the same manner, a description of one side is sufficient.

At the other end of the pulley shaft G is a pinion S giving motion to a spur wheel T, to which is joined a pinion U; this combined wheel and pinion T U works upon a stud V, imparting motion by means of a spur wheel W to a shaft X; upon this shaft are placed two heart-shaped cams Y, communicating a reciprocating motion by means of connecting rods Z to the rocking beam a, to which are suspended by varying links b the galleries c, in which are placed the holders d for holding the flax during the process of hackling; e are the pawls, f are the vertical bars fastened into the levers g, h is the connecting rod connecting the two levers together, f is the grooved pulley or wiper for giving the forward and backward motion, f are guide bars fitted to the upper and lower belt or sheet drum shafts, for the purpose of keeping the hackling bars and hackles in At the other end of the pulley shaft G is a pinion purpose of keeping the hackling bars and hackles in The hackle bars E are formed of angle iron, the

The hackle bars E are formed of angle iron, the angle being the same as that of the hackles, viz., from 70deg. to 80deg. The method of fixing the hackle bars to the belts or sheets is by screw pins, as shown in fig. 4. Upon the hackle bars E are fixed the hackle stocks F, and screwed thereto by screw pins, as shown also in fig. 4. The stripping bars k, figs. 4, 5, 6, 7, 8, are formed of malleable iron; their ends are riveted to brass guides l which move in and out of the recesses m formed for them in each of the hackling stocks F, the travel of these end of the hackling stocks F, the travel of these guides being such that when the stripping bar k is at its outer position it is about level with the points of the hackle pins, as shown in figs. 4 and 6, and when at its inner position projecting a little beyond the hackle stock F, as seen in figs. 5 and 7.

When the machine is at work, the stripping bar k,

before striking the flax, is at its outward position, as shown in fig. 4, but as the flax descends and meets this stripping bar, it forces the latter to its inner position, as shown in fig. 5; it then presses against the fibre when being operated upon, and keeps it in firm contact with the opposite row of pins, which is a material advantage. As soon, therefore, as it leaves the fibre, it shifts, by its centrifugal force, again to its former outward position. In doing this it completely clears the hackles of the tow and other extraneous matter, leaving them clean for the next operation.

Mr. Rowan also proposes another mode of work-Mr. Rowan also proposes another mode of working the stripping bars, the attachment of the various parts being similar to the mode already described, but instead of the centrifugal force of action being applied to the stripping bars, springs are used, which are acted upon by coming into contact with the lower belt drum B which pushes the bar to its outward position, shown at T, fig. 9: after the hackle bar has cleared itself from the drum, the spring, becoming free, brings back the stripping bar to its original inner position, preparatory to the next operaoriginal inner position, preparatory to the next opera-tion of hackling, shown at H in the same figure.

#### THE LUMINOUS SEA.\*

CURIOSITY has not been oftener excited with the phenomena of nature, nor with more pleasing sensations to those who have witnessed its full its full effects, than by the luminous appearance of the In the tropical regions where nature spreads her richest treasures, this phenomenon is seen in its greatest splendour, and the mariner, with no great stretch of the imagination, has often fancied himself in a sea of liquid fire. On the coast of Mexico, in the Pacific Ocean, during the calm of night, when stars are only visible above, the sea has assumed this appearance to such a degree that a ship actually this appearance to such a degree that a ship actually seems to be floating in a bed of sparks of active fire, and as she rises with the surface swell, or dashes it from her by any sudden effect of a wave, it curls from off her sides as a sheet of fire throwing a bread glare of light. This appearance so gratifying to the eye is sufficient to fill the mind of the person who may be contemplating it with wonder and astonishment, and the cause of it is naturally his first question. That it proceeds from animalculæ is generally known; but their nature and the circumstances under which the light is omitted is with many persons still a matter of speculation. We have, stances under which the light is omitted is with many persons still a matter of speculation. We have, therefore, considered it a subject worthy of attention, and shall lay before our readers some account of this curious phenomenon. The first we take from the philosophical transactions of the Royal Society, and the Manufacture of Limitons of the Royal Society of th entitled "Mr. Macartney's Observations on Luminous Animals," and although his paper was read long ago it has all the interest of yesterday, and is as

The property which certain animals have of The property which certain animals have of emitting light is so curious that it has attracted the attention of naturalists in all ages. It was particularly noticed by Aristotle and Pliny among the ancients, and the publications of the different

learned societies of Europe contain numerous memoirs on the subject. Notwithstanding the degree of regard bestowed on the history of luminous animals, it is still very imperfect. The power of producing light appears to have been attributed to several creatures which do not possess attributed to several creatures which do not possess it. Some species which enjoy it in an eminent degree, have been imperfectly described or entirely unobserved. The organs which afford the light in certain animals have not been examined by dissec-

certain animals have not been examined by dissection; and, lastly, the explanations which have been given of the phenomena of this light are unsatisfactory, and in some instan es palpably erroneous. As this subject forms an interesting part of the history of organized beings, I have for some years availed myself of such opportunities as have occurred for its investigation. Having communicated the result of some of my researches to the Right Honourable Sir Joseph Banks, he immediately offered me his assistance with that liberality which so eminently distinguishes him as a lover of science. offered me his assistance with that liberality which so eminently distinguishes him as a lover of science. I am indebted to him for an inspection of the valuable journal he kept during his voyage with Captain Cook; for permission to copy the original drawings in his possession of those luminous animals discovered in both the voyages of Cook and for some notes on the luminous experance. animais discovered in both the voyages of Cook and for some notes on the luminous appearance of the sea that were presented to him by Captain Homsburgh, whose accuracy of observation is already known to this learned society.

In the following paper I shall first examine the grounds on which the property of showing lights has been ascribed to certain animals, which either do not presess it or in which the existence is quaetion.

has been ascribed to certain animals, which either do not possess it or in which its existence is questionable. I shall next give an account of some luminous species of which some have been inaccurately described, and others quite unknown. I shall endeavour to explain from my own observations, and the information communicated to me by others, many of the circumstances attending the luminous appearance of the sea. I shall then describe the organs employed for the production of light in certain species; and, lastly, I shall review the opinions which have been entertained respecting the nature and origin of animal light, and relate the experiments I have made for elucidating this part experiments I have made for elucidating this part the subject.

of the subject.

The property of emitting light has been reported to belong to several fishes, more particularly the mackerel, the moon fish (Tetradon ircola), the dorado, mullet, sprat, &c. M. Bajon observed during the migration of the dorados, that their bodies were covered with luminous points. These points, however, proved on examination to be minute spherical particles that adhered to the surface of these fishes; and, he adds, appeared to be precisely the same sort of points that illuminated the whole of the sea at the time. They were, therefore, in all probability, the minute kind of medusa which I shall have occasion to describe hereafter. Godehan de Rivilla, states in a paper sent to the Academy of Sciences at Paris, that on opening the Scomber polamus he found in different parts of its body an oil which gave out much light.

to the Academy of Sciences at Paris, that on opening the Scomber polamus he found in different parts of its body an oil which gave out much light. But it should be observed that Rivilla had a particular theory to support for which this fact was very convenient, and that other parts of his memoir bear marks of inaccuracy. It may be added that if the oil of fishes were usually luminous, which Rivilla supposed, it would be almost universally known, instead of resting on a solitary observation.

As far as I am able to determine from what I have seen, the faculty of exhibiting light during life does not belong to the class of fishes. It appears probable that some fishes may have acquired the character of being luminous, from evolving light soon after death. Some species of lepas, nurex, and channa, and some star-fish, have been known to possess the power of shining; and the assertion has been repeated by one writer after another; but without quoting any authority. Bringueire saw on one occasion, as he supposed, common earthworms in a luminous state: all the hedges were filled with them; he remarked that the light resided in the posterior part of the body. Hanguerges pretended to have seen earthworms luminous in three instances; it was each time in October; the body shone at every part, but most brillantly at the gonital organs. it was each time in October; the body shone at every part, but most brillantly at the genital organs. Notwithstanding this concurrence of testimony, it is next to impossible that animals so frequently before our eyes as the common earthworm, should be endowed with so remarkable a property without every person having observed it. every person having observed it.

In different systems of natural history the In different systems of natural history the property of shining is attributed to the Cancer pulex. The authorities for this opinion are Hablitzl, Thules, and Bernard. The fermer observed on one occasion a cable, that was drawn up from the sea, exhibit light, which on closer inspection was proved to be covered with these insects. Thules and Bernard reported that they met with a number of this species of cancer on the borders of a river, entirely luminous. I am nevertheless disposed to question the luminous property of the Cancer pulex, as I have often had the animal in my possession, and never perceived it emit any my possession, and never perceived it emit any light. The account given by Linneus of the Scolopendra phosphorea is so improbable and inconsistent, that one might be led to doubt the

· From the " Nautical Magazine."

existence of this insect; particularly as it does not

existence of this insect; particularly as it does not appear to have been ever seen except by Ekaberg, the captain of an East Indiaman, from whom Linneaus learned its history.

I now proceed to the description of those luminous animals that have been discovered by Sir Joseph Banks, Captain Horsburg, and myself. On the passage from Madeira to Rio Janeiro the sea was observed by Sir Joseph Banks to be unusually luminous, flashing in many parts like lightning. He directed some of the water to be hauled up, in which he discovered two kinds of animals that occasioned the phenomenon: the one a crustaceous insect which he called the Cancer fulgens, the other a large species of medusa to which he gave the name of pellucens.

The Cancer fulgens bears some resemblance to

The Cancer fulgens bears some resemblance to the common shrimp. It is, however, considerably less:
the legs are furnished with numerous seta (hair or bristles). The light of this animal, which is very brilliant, appears to issue from every part of its

body. The Medusa pellucens measures inches across the crown or umbella (round head

containing the seed). This part is marked by a a number of opaque lines that pass off from the centre to the circumference. The edges of the umbella is divided into lobulas which succeed each other; one large and two small ones alternately. From within the margin of the umbella, there are suspended a number of long cord-shaped tentacula. The central part of the animal is opaque, and furnished with four thick irregularly shaped processes, which hang down in the midst of the tentacula. This zoophyte is the most splendid of the luminous inhabitants of the ocean. The flashes of light emitted during its contractions are so vivid as to affect the sight of the spectator.

In the notes communicated to Sir Joseph Banks by Captain Horsburg, he remarks that the luminous

by Captain Horsburg, he remarks that the luminous state of the sea between the tropics is generally accompanied with the appearance of a great number of marine animals of various kinds on the surface of the water, to many of which, however, he does not the water, to many of which, however, he does not attribute the property of shining. At other times when the water which gave out light was examined it appeared to contain only small particles of a dusky straw colour, which dissolved with the slightest touch of the finger, He likewise observes that in Bombay during the hot weather of May and June he has frequently seen the edges of the sea illuminated by minute specifier points. illuminated by minute sparkling points.

At sunrise on the 12th of April, 1798, he perceived

several luminous spots in the water, of which spots,

conceiving them to be animals, he went in a boat and caught one. It proved to be an insect some-what resembling in appearance the wood-louse, and was about one-third of an inch in length. When was about one-third of an inch in length. When viewed with a microscope it seemed to be formed by sections, of a thin crustaceous substance. During the time that any fluid remained in the animal, it shone brilliantly like the firefly. In the month of June of the same year, he picked up another luminous insect on a sandy beach that was also covered with a thin shell, but it was of a different shape, and of a larger size than the animal taken in the Arabian Sea. Comparing the above description with a neat pen and ink sketch made by Captain Horsburg, and which accompanied his paper, I have no doubt that both these insects were monoculi. The first evidently belongs to the genus Limulus of

I shall therefore beg leave to distinguish

Muller. I shall therefore beg leave to distinguish it by the name of Linulus Nocticulus.

My pursuits and the state of my health having frequently led me to the coast, I have had many opportunities of making observations on the animals which illuminate our own seas. Of these I have discovered three species, one of which is a veroe, not hitherto described by authors, enother serves.

authors: another agrees so nearly with the Medusa hemispherica, that I conceive it to be the same, or at least a variety ofthat species. The third is a minute species of Medusa, which I believe to be the luminous animal so frequently seen by navigators; although it has never heen distinctly examined or described. It is drawn

been distinctly examined or described. It is drawn here magnified to about twelve times its natural size. I first met with these animals in the month of October, I first met with these animals in the month of October, 1804, at Herne Bay, a small watering place on the north coast of Kent. Having observed the sea to be extremely luminous for several nights, I had a considerable quantity of the water taken up. When perfectly at rest no light was emitted, but on the slightest agitation of the vessel in which the water was contained, a brilliant scintillation was perceived, particularly towards the surface. When the vessel was suddenly struck a flesh of light issued from the vas suddenly struck, a flash of light issued from the top of the water, in consequence of so many points shining at the same moment. And when any of these sparkling points were removed from the water, they no longer yielded any light. They were so transparent that in the air they appeared like globules of water, They were so minute as to be even less than the head of the smallest pin. On the slightest touch they broke and vanished from the

sights. Having strained a quantity of the luminous water, a great number of these transparent corpuscules were obtained upon cloth, and the water which had been strained did not afterwards exhibit the least light. I then put some sea-water that had been rendered particularly clear by repeated of the strain into a large glass vessel, and having filtration, into a large glass vessel, and having floated in it a fine cloth on which I had previously collected a number of luminous points, several of collected a number of luminous points, several of them were liberated, and became distinctly visible in their natural element, by placing the glass before a piece of dark coloured paper. They were observed to have a tendency to come to the surface of the water, and after the glass had been set aside for some time, they were found congregated together, and when thus collected in a body they had a dusky straw colour; although individually they were so transparent, as to be perfectly invisible, except under particular circumstances. Their substance, indeed, was so extremely tender and delicate, that they did transparent, as to be percently in the particular circumstances. Their substance, indeed, was so extremely tender and delicate, that they did not become opaque in distilled vinegar or alcohol until immersed in these liquors for a considerable

On examining these minute globules with the microscope, they proved to be not quite perfect spheres. They had an irregular depression on one side that was formed of an opaque substance that receded rather inwards, producing such an appearance of the substance of a round receded rather inwards, producing such an appear-ance as would arise from tying the neck of a round bag, and turning it into the body. The motions of these creatures in the water were slow and graceful, and not accompanied by any visible contractions of their bodies. After death they always subsided to the bottom of the vessel. From the sparkling light afforded by this species, I shall distinguish it by the name of Meduas scintillans. On the night after that in which I discovered the

by the name of Medusa scintillans.

On the night after that in which I discovered the preceding animal, I caught two others of the luminous species. One of these I call the Beroe fulgens. This most elegant creature is of a colour changing between purple, violet, and pale blue. The form of it is difficult to assign as it is varied by partial contraction at the animal's pleasure. I have represented here the two extremes of form which I have seen this creature assume. The first partial contraction at the animals pleasure. In have represented here the two extremes of form which I have seen this creature assume. The first is somewhat that of a cucumber, which being that which it takes when at rest should perhaps be considered as its proper shape. The other is that of a pear. The body is hollow, or forms internally an infundibealar cavity, having a wide opening before, and it appears also to have a small aperture posteriorly. The posterior part, and indeed two-thirds of the body, are ornamented with eight longitudinal ciliated ribs, the process of which are kept in such rapid rotatory motion while the animal is swimming, that they appear like the continual passing of a fluid along the ribs. The ciliated ribs have been described by Professor Mitchell

ciliated ribs have been de-scribed by Professor Mitchell as arteries in a luminous Beroe, which I suspect is no other than the species of which I am giving this

account.

When the Beroe fulgens swarm gently near when the Beroe ruigens swarm gently hear the surface of the water, its whole body became occasionally illuminated in a slight degree. Dur-ing its contractions a stronger light issued from the ribs, and when a sudden shock was communicated to the water which contained several of these animals, a vivid flash was thrown out. If the body were broken, the fragments continued luminous for some seconds, and being rubbed on the hand left a light like that of phosphorus. This, however, as well s every other mode of emitting light, ceased after he death of the animal.

The hemis herical species that I discovered had a very faint purple colour. The largest that I found measured about three-quarters of an inch in diameter. The margin of the umbella was un-

three-quarters of an inch in diameter. The margin of the umbella was undivided and surrounded internally by a row of pale brown spots, and numerous small twisted tentacula Four opaque lines crossed in an arched manner from the circumference towards the centre of the animal. An opaque irregularly shaped process hung down from the middle of the umbella. When this part was examined with a lens of high power, I discovered that it was enclosed in a sheath in which it moved. that it was enclosed in a sheath in which it moved. The extremity of the process was found to be divided into four tentaculas, covered with little cusps or suckers, like those on the tentacula of the cuttle

suckers, like those on the tentacula of the cuttle fish.

This species of Medusa bears a striking resemblance to the figures Medusa hemispherica published by Grouoviers and Muller. Indeed, it differs as little from these figures as they do from each other. Its luminous property, however, was not observed by these naturalists, and this is the more extraordinary as Muller examined it at night, and says that it is so transparent it can only be seen by the light of a lump. If it should still be considered as a distinct species, or as a variety of the hemispherica, I would propose to call it the Medusa lucida. In this species the central spot and the part round the margin are commonly seen to shine on lifting the animal out of the water into the air, when it presents the appearance of an illuminated wheel. And when it is exposed to the usual percussion of the water, the transparent parts are alone luminous.

(To be continued.)

#### NEW YORK SOCIETY OF PRACTICAL ENGINEERING.

T the regular semi-monthly meeting of this A T the regular semi-monthly meeting of this Society, at the Cooper Institute, on the 24th of November, 1868, James A. Whitney presiding, the subject of Elevating Machinery was taken up, and a paper on this topic was read by Mr. T.P. Pemberton, in which he gave an extended history of ancient and modern devices used for raising heavy bodies, such as massive hewn stones in the walls of ancient edifices, and showed how the great bronze statue of St. Petersburgh and its solid pedestal, weighing about 1,000 tons, were moved to their present locality. The writer spoke of the windlass in its present rude form, as used over wells and mining pits, and stated that it was even yet used on Chinese junks, and was in vogue on English vessels not over 100 years ago; and showed how the present capstan had by successive steps of improvement superseded that device, and graphically described the similarity of the song of the sailors in all ages while heaving upon the anchor chains with whatever machinery they employed. He then proceeded more specifically to point out the most conspicuous and approved hoisting apparatus used in modern times, and gave a detailed account of the immense cranes employed in foundries, where great masses of molten metal had to be conveyed to the moulds, and in locomotive works where, in England, they lift an entire engine weighing twenty tons, over a dozen others, and move it from one end of the building to the other. He then called attention to the different elevating devices used in hotels for conveying persons and baggage from one floor to another, and spoke of the necessity of absolute safety wherever human life was jeopardized. He pointed out numerous accidents in hotels and deep mining shafts from the breaking of ropes or the giving way of some portions of the machinery, and urged the necessity of employing stops or safety pawls in all rope elevators, that would not fail to come into play whenever the rope or machinery failed to act. He showed the different kinds of lifting force employed, and condemned the use of ropes, either wire or hempen, as unsafe, and thought the screw only could insure absolute safety. He closed his paper by eloquently describing the onward strides of mechanical progress in subjecting matter to mind and the superiority of science over brute force.

The reading of the paper gave rise to a very interesting discussion on collateral subjects, in which a number of gentlemen took part. Dr. A. W. Hall referred to the well-known historical fact of immense stones, weighing not less than 800 tons, being raised and placed in the walls of ancient aqueducts 50ft. above the ground by machinery unknown to the present generation, and which would be impossible by any hoisting device now

He described on the blackboard how he in use. supposed such results were accomplished. By placing two fulcra supports under the stone, near and on either side of the centre, it could be alternately tilted at either end, while the released fulcrum was raised and underbuilt with masonry, and in this way two men might lift such a stone to any reasonable height, only give them time enough.

The solution of the problem was received with ap-

plause by the audience.

Prof. Holmes explained an English hoisting machine in use in some of the deepest coal mines, which consisted of two series of platforms about 15ft. above each other, secured to timbers extending from top to bottom of the shaft. These timbers were attached to the two ends of a beam engine at the top of the shaft, the movement of which would alternately raise one set of platforms and lower the other. All that a gang of men had to do was to step from one platform to the other, as the walking beam brought them into juxtaposition, and in this way 500 men at a time could ascend or descend a shaft without danger, as it was not possible to fall further than 15ft. if a platform gave way.

Mr. Manner gave an exhibition of his patent Arion pianoforte, and explained its peculiarities.

These relate to the manner of stringing the instrument, and supporting the strain upon the case by a newly arranged iron frame, with an extra bar between the under and over strings. It produced a remarkable volume and brilliancy of tone.

The Society then adjourned for two weeks, after the chair had announced the subject of "Mining Machinery" as the next paper in order.

#### PRINTING TEXTILE FABRICS.

PRINTING TEXTILE FABRICS.

A N invention recently patented by Mr. John Lightfoot, of Lower House, near Burnley, consists in applying to textile fabries or yarns, particularly those made from cotton or linen, certain indigo preparations simultaneously with the usual mordants for dyeing. The indigo preparations undergo the usual operations of dyeing and clearing along with the mordants, the result being that blues, greens, and other shades are produced along with the colours obtained by dyeing mordants with dye stuffs. The use of indigotine, combined or mixed with an oxide or salt of tin, for producing blue figures upon cotton or linen fabrics, and subsequently raising these colours in an alkaline bath, is well known to calico printers under the name of fast blue; or when mixed with a salt of lead under the name of fast presen. When applied in madder or garancine styles these colours have been usually blocked into spaces left vacant for them after the pieces have been printed, dyed, cleared, and dried. From time to time attempts have been made to print simultaneously with the madder and garancine mordants, preparations of indigo, and, in some cases, those named above as fast blue and fast green, so as to save the expense of blocking in these colours after dyeing. But either from the blues and greens so produced having been dull and wanting in vivacity, or from the mordants having been attacked by the alkaline bath used to fix the indigo colours, and the dyed colours thus coming from the bath poor and bare, or from special apparatus having been necessary to print the indigo colours, these attempts have never met with success. The discovery, therefore, of an efficient process which will enable the simultaneous printing of blue and green with mordants intended for dyeing to be successfully carried into practice was and remained a desideratum up to the present time. Mr. Lightfoot has succeeded in discovering that the difficulties which have prevented success hithertomay be obviated by using the indigo preparations.

for dyeing to be successfully carried into practice was and remained a desideratum up to the present time. Mr. Lightfoot has succeeded in discovering that the difficulties which have prevented success hitherto may be obviated by using the indigo preparations, and by employing for fixing indigo blue and green in juxtaposition with ordinary madder mordants materials presently mentioned, these materials not having been so used before.

This process enables the operator to produce fine blues and greens, which are printed at the same time as the ordinary mordants for reds, purples, chocolates, and black, and undergo with them the operations required to dye and clear these colours. Mr. Lightfoot makes a preparation of indigo, fulfilling the required conditions by employing much less tin, whether as oxide or in the state of salt, in the process of dissolving the indigo than has hitherto been used, and also by dispensing with the addition of a salt of tin to the precipitated indigotine, whether this has been made by the aid of oxide or salt of tin, or, as is sometimes the case, by the aid of metallic tin, because he has ascertained that if the tin is in excess of a certain proportion to the indigo, oxide of tin is left in the fibre during the process of fixing the indigo colours and the mordants, and thus acting itself as a mordant, becomes dyed by the dye stuff, producing with the indigo compound colours. oxide of tin is left in the fibre during the process of fixing the indigo colours and the mordants, and thus acting itself as a mordant, becomes dyed by the dye stuff, producing with the indigo compound colours, which in the case of blue are more or less purple and dull, and in the case of green are more or less a sombre olive. This use of tin in excess has been "Martyrs of Garinchum."

one of the causes of the failures to which we have

one of the causes of the failures to which we have before alluded.

Mr. Lightfoot prepares a paste or pulp of indigotine and tin suitable for his improved process by the following method:—He takes of dry indigo in a ground or powdered state, 14lb., or when indigo pulp is used, using such a quantity as to be equal to 14lb. of dry indigo, of protochloride of tin in crystals 14lb., and of caustic soda at 30deg. on Twaddell's hydrometer, or of caustic potash at 40deg. on Twaddell's hydrometer, I gallon. These materials are put in a pan and raised to boil in half an hour, and 1 gallon of boiling water is then added. The mixture is now allowed to become perfectly cold, and 3 gallons of cold water, in which are dissolved 8oz. of sugar, or 1lb. of treacle is poured into it. To this solution is added 2½ pints of muriatic acid at 32deg. of Twaddell's hydrometer, or 1 pint of sulphuric acid of commerce, previously diluted with 1 pint of water, and allowed to stand till clear, or 3 quarts of acetic acid at 8deg. of Twaddell's hydrometer.

The indigotine may also be precipitated by a mixture of protochloride of tin solution at 120deg. of Twaddell's hydrometer, with any of the acids named, using one quarter of a pint of tin solution, and only half the quantities of the acids given above, this quantity of tin solution being the maximum that can be used when precipitating the indigotine for producing a fine blue and green. Instead of using protochloride of tin crystals in making the indigo solution, protoxide of tin made by precipitating a solution of protoxalt of tin with an alkali may be used, the precipitate being washed with water and filtered to a thick paste, or anhydrous protoxide of tin made in any convenient way may be employed, in all cases taking such a proportion of oxide as shall contain an amount of tin about equal to but not greater than that in 14lb. of crystallized protochloride. In some cases the mixture of 14lb. of indigo and 1 gallon of alkali may be boiled with metallic tin in powder or granulated, the qua there shall be metallic tin undissolved. In all these cases the indigotine is precipitated as previously described, and the precipitate is filtered through a deep conical filter so as to leave as small a surface exposed to the air as possible.

to the air as possible.

To make a blue colour for printing, take 4 gallons of indigotine precipitate and 14lb. of gum senegal in powder, stirring until dissolved; after straining, the colour is ready for printing. To make a green colour, take 41 gallons of indigotine pulp and 18lb. of gum senegal in powder, stir till dissolved, and add 11lb. of nitrate of lead in powder, and 11lb. of white acetate of lead in powder, stir till dissolved and strain.

Compound colours may be made by mixing the Compound colours may be made by mixing the blue and green colours with each other or with the ordinary mordants for dyeing. With the blue and green above described, and the ordinary ferruginous and aluminous mordants, Mr. Lightfoot prints cotton and linen fabrics, and after cooling, hangs the pieces in an ageing room for one night; they then undergo the fixing operation by passing them into a solution of silicate of soda or silicate of potash at 8d g. of Twaddell's hydrometer, or into a solution of carbonate of potash at 12deg. of Twaddell's hydrometer, to which about 1oz. of chalk in powder per gallon may be added, or into a mixture of silicate of soda or silicate of potash at 8deg. of Twaddell's hydrometer with carbonate of potash at 12deg. of Twaddell's hydrometer. The bath is heated to 90deg. Fah. or thereabouts in a cistern fitted with rollers at the top and bottom, and the passage of the 90deg. Fah. or thereabouts in a cistern inted with rollers at the top and bottom, and the passage of the pieces may be at the rate of 25 yards per minute. On leaving this the pieces must be quickly winced in a pit of cold water fitted with a reel about 4ft, above the surface of the water. By this wincing the indigotine attached to the fibre becomes again indigotine.

Indigotine attached to the libre becomes again indigo blue.

If green has been printed, the pieces are next passed into a solution of bichromate of potash containing loz. of bichromate of potash per gallon of water at 100deg. Fah. for five minutes; the goods are then washed. If only blue has been printed along with the mordants this process may be omitted. The pieces are next subjected to the operation known to calico printers as "second dunging," and which consists in making the pieces circulate in a beck containing cowdung and water at a temperature of about 160deg. Fahr. for from fifteen to twenty minutes. They are then washed with water and dyed with madder, munjeet, flower of madder, garancine, extract of madder, cochineal, mixtures of garancine with sumac and bark, or with either of them, after which the ordinary operations of clearing the white grounds may be performed, preference being given to the chloride of line clearing unallys adopted with garancine colours.

## Correspondence.

THE OSCILLATORY MOVEMENT OF THE EARTH.

TO THE EDITOR OF THE "MECHANICS MAGAZINE."

Sir,—In the many theories that have been brought forward, I cannot find one that sufficiently explains what may be called "the oscillatory movement of the earth." It may be premature to further advance the theory that a planet increases in gravity, and consequently in orbit, at the expense of the central bedy until by couler demonstration, these doubtes consequently in orbit, at the expense of the central body, until, by ocular demonstration, those doubts which still cloud the mind of the scientific world shall be removed. But as all doubts have long since vanished from the mind of the writer, allow him to offer a remark upon the subject in advance of the telescope. The oscillatory movement of the earth results from the alternate accumulation of the solar deposits upon each side of the equator—which is the elucidation of the phenomena of the seasons. The question arises,—whether, from the preponderance of land north of the equator and on the side where the ocean is the principal recipient, there is not an inequality in the gravitating medium? Such being the case, we must admit a gradual change in the line of the equator. This, combined with the gradual subsidence of internal heat, may account not only for the position of fossil remains, but assist in the elucidation of questions that have long baffled philosophical research. The exact accordance in the sophical research. The exact accordance in the oscillatory movement of the earth with its orbit ought to be a question of great importance. The error of modern science appears to consist in the misconception of an original cause.—I am, Sir, yours, &c.,

H. Saloway. yours, &c.,

#### THE SOLID LEVER BRIDGE.

SIR,—In your number of June 26 last, you drew the attention of your readers to what, in America, appears to be a new method of constructing a bridge. I beg to enclose a photograph which represents the

I the Limits bridge in common as in the franciacan in mutains, and in Cashmere. It appears to me to be identical with the bridge that you describe, as far as solid levers are concerned. In a country where iron is extremely valuable and difficult to procure, the utility of these bridges is very great. The abutments are composed of alternate layers of rough stone and the bridge is constructed without the timber, and the bridge is constructed without the use of an ounce of metal.—I am, Sir, yours, &c.,
Madras, November 23. H. C. W.

#### TO CORRESPONDENTS.

GEORGE SIMON HARCOURT, Esq. (nee Ainslie), of the 69th Foot, and afterwards with the 1st or Royal

the 69th Foot, and afterwards with the 1st or Royal Dragoous, one of the few remaining officers who served at the battle of Waterloo, died, on December 29, at Bedford, at the age of 72.

CAPTAIN TALBOT, of the "Star of Hope," has been presented with a gold chronometer watch, by Captain Munro, Mr. Brown, and the others who were rescued from the wreck of the "Hibernia." A movement has been set on foot in Edinburgh and Leith to present Captain Talbot with a public testimonial. mouial.

monial.

The Lords of the Admiralty have directed that a report shall be prepared of what is likely to be the expense of converting the wooden line-of-battle ship "Cumbriland," late guardship of the steam reserve at Sheerness and Chatham, into a training-ship for boys, If it should be determined to carry out the idea, the "Cumberland" will be stationed in the Cludo.

THE attention of the Secretary of War having been directed to the large expenditure incurred by the military and civil departments of the army in telegraphic messages, an order from the War De-partment has been issued directing that the utmost caution be observed in the recourse to this mode of communication, which should be adopted only in cases where the delay involved in a letter by post would really prove prejudicial to the public service.

Sir P. Francis has recommended Alex. Nair, one

of the crew of the barque "Tyne," lost off the Island of Marmora, to the Foreign Office for some suitable reward for his courage on the occasion. The vessel was wrecked about half a mile from the shore of the island, and the brave fellow swam ashore with a light line, which enabled him to land a cable, along which the captain and the remainder of the crew effected their escape.

The Board of Trade have determined to present

a binocular glass to Captain Rumball, master of the American brig "Dirigo," in acknowledgment of the American brig "Dirigo, in acknowledgment of the humanity shown by him in rescuing the mate and five scatnen of the "John Duncan," of St. John's, N.B., wrecked in a hurricane in November last. The only survivors on board the "John Duncan" (the rest having been washed overboard), were nine the rest having been in a most distressed condition for twelve days, when they were taken off the wreck by the American ships "Rabbon" and "Drigo." IT appears that the port of Trouville, opposite Havre, across the mouth of the Seine, is being

Havre, across the mouth of the Seine, is being adapted to receive the largest ships, and that from a mere fashionable bathing place it is to become a chief point in transitu between England the southwest of France. It is ninety-five miles less from Trouville to Bordeaux, via Mans than from Havre to Bordeaux. Arrangements have already been made at Trouville for receiving large supplies of English coal, destined for Normandy, and the departments to the south of it. to the south of it.

the meeting of the Chatham Local Board of Health last Friday they had under consideration the necessity which exists, both in connection with the military and naval establishments as well as for the military and navai establishments as we as for ine public in general, for an electric time gun to be fired daily, as is the case at many of the other large military and naval stations, in order that correct Greenwich time may be notified. The Board unanimously decided to apply to the Government on the subject, and a deputation was appointed to wait on the authorities to request that the necessary arrangements might be made.

A FIRE broke out in Fort Lafayette, New York Harbour, on December I last, which resulted in the destruction of all the combustible part of the structure. It appears that a party of labourers in the employ of the engineer department, were engaged in putting a shed over the casemates, and that at dinner time one of them built a fire in a regular fireplace for the purpose of warming his coffee. Sparks from this fire fell on the roof, which conce. Sparks from this fire fell on the roof, which was soon in a blaze, the flames spreading to the large quantity of lumber then in the Fort to be used in making a roof. Owing to a want of suitable appliances for extinguishing such a fire, the flames only ceased their work when they had nothing more to feed upon.

MR. MARTELL, the newly-appointed chief surveyor MR. MARTELL, the newly-appointed chief surveyor of Lloyd's on the Tyne, has just completed his returns of shipbuilding on the Tyne for the past year. From the statistics we find the tonnage launched has exceeded by more than 50 per cent. the figure of the previous year, 1867. This is accounted for by the fact that considerable impetus has of recent years been given to the eastern trade, and there has been a demand for new years), of and there has been a demand for new vessels of larger tonnage and higher class. There has also been an increase for first-class steamers with capitalists, while there has been a gradual declension in sailing vessels. According to the returns just published, fifty-eight vessels have been built, with a grass tonnage of 25 604 tons average tonnage. a gross tonnage of 25,694 tons; average tonnage, 525. Last year the number of vessels built was thirty-four; gross tonnage, 16,224; average tonnage, 477. It will thus be seen that in 1868 ship-building on the Tyne was decidedly better than in the preceding year.

## Miscellanea.

A GOOD specimen of the spoonbill was shot on the 21st ult., at Benacre, in Suffolk. These birds are rare visitors to this country.

A FRENCHMAN has observed that when the hori-

zontal branches of a vine are attacked with oidium, those that are vertical are in most cases free from it.

NEARLY half-a-dozen towns in Cornwall that do not enjoy railway communication, will, in the course of a week or two, participate in the advantage of the electric telegraph.

A RARE Hebrew Bible, of the Naples edition of

A RAKE Hencew Bible, of the Naples edition of 1491 or 1492, printed upon vellum, was recently sold at Puttick and Simpson's, Leicester-square, after a smart competition, for £160.

MARSHAL VAILLANT, Minister of the Emperor's Household, and of the Fine Arts, has given a site on the territory of the Depot of Marbles, for the erection of the model of the railway bridge from Calais. tion of the model of the railway bridge from Calais

A YEAR since, the number of Chambers of Agriculture established in Great Britain was 36, now it has increased to 70. At the close of 1867 the aggregate number of members enrolled was 10,000, now it has increased to 16,000.

THE Chamber of Commerce and Arts of the pro-

THE Chamber of Commerce and Arts of the province of Coni has addressed a letter to the Emperor Napoleon, soliciting his Majesty's support for a tunnel through the Col di Tenda, so as to bring France and Italy nearer in that quarter.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending January 2, was 12,742. Total number since the opening of the Museum free daily (May 12, 1858), 1.469.309 1.469.309.

A serious landslip has occurred at Dartmouth. Several tons of earth and rock have fallen at the Castle, filling up the cove and destroying the footpath

Castle, filling up the cove and destroying the footpath leading to that romantic place. It is feared that a further slip will take place.

At a recent meeting of an engineering society in New York, Dr. J. V. C. Smith, of Boston, described an antique water-wheel, which he had seen at work sin one of the gorges of the Lebanon mountains, and of which the Arabs said that the same kind had been in nearly that country for a gos.

in use in that country for ages.

Mr. Fell. C.E., has offered to the Swiss Federal MR. FEIL. C.E.. has offered to the Swiss Federal Council to undertake the construction of three rail-roads over the Alps for a guarantee of interest of 600,000f, annually. He estimates the cost of that over the Simplon at from 11 to 13 millions; of the St. Gothard at from 13 to 14; and at 15 to 18 for the Luckmanier.

THE galleries of Greek and Roman sculpture in the Louvre have been largely increased and embellished of late, and amongst the ornaments introbetitshed of late, and amongst the ornaments intro-duced are a number of bas-reliefs, round bosses, and allegorical figures, covered with a coating of metal, the work of M. Cossinus. The effect of these electrotype bronzes is extremely rich, while the cost

is trivial compared with real bronzes.

Some months ago, Mr. Robert Metcalfe, of Malton, was commissioned by one of the largest landowners in Prussia to send out two Leicester rams for the first season. These sheep did so well that Mr. Metfirst season. irst season. These sheep du so wen that Mr. Mel-calfe has received a similar order. He has again selected two rams from the well-known Barton flock. The sheep are this time the descendants of the famous Sir Tatton, which won thirty-six first pre-

THE number of visitors to the South Kensington The number of visitors to the South Kensington Museum ending January 2, 1869 (Christmas week), open free from 10 a.m. to 10 p.m., daily 34,045; Meyrick and other galleries 8,122; total—42,167. Average of corresponding week in former years, 24,417. The total number of visitors during the year ending December 31, 1868, has been—morning, 599,143; evening, 281,033, making a total of \$81,076, or 234,560 over the preceding year. Total from opening of Museum—8,013,164.

The week before last, a number of salmon were caucht in a small tributary of the Usk for the

caught in a small tributary of the Usk for the purpose of obtaining spawn for New Zealand. The successfully conducted by operations were very successfully conducted by Neville, from Mr. Buckland's museum in the Horticultural Gardens, and in a few hours about \$5,000 salmon ova were secured. Mr. Berrington,

the chairman, Mr. Lloyd, and the superintendent of water builiffs were present. The ova have been since carefully packed by Mr. Youl in eighty-one boxes, on board the ship "Mendora," in the London

WE understand that arrangements have been made between a number of gentlemen interested in the subject whereby Mr. Fairlie's four cylinder, double bogie locomotive will shortly be introduced, in its most improved form, in regular work upon one or more English lines. A number of these engines are most improved form, in regular work upon one or more English lines. A number of these engines are now in course of construction in the States for various lines there; among others, for the Central Pacific Railway of California which rises 7,042ft, in a distance of 105 miles, with long gradients of a maximum inclination of 1 in 45<sub>1</sub>.

Mr. James Allison Hogg, gas engineer, Edinburgh, has discovered a method of producing intense light with coal gas by mixing it with atmospheric air. The mixture of gases is lighted after passing through a tissue of iridio-platina wire at a determined pressure. In a few seconds the metal becomes heated up to a white heat, the flame

metal becomes heated up to a white heat, the flame metal becomes heated up to a white heat, the flame disappears, and an intense white light is the result. An enlarged picture has been taken by its aid on prepared photographic paper. The light will burn in a gale of wind without any protection round it, and a downpour of rain will not affect it.

MR. Benson has just fitted up in the front of his premises in Ludgate-hill three most useful indicators —viz. a clock perpetual calendar, and wind dial.

viz., a clock, perpetual calendar, and wind dial. The clock occupies one window, the perpetual calendar another. This consists of three dials, and is a most ingenious piece of mechanism, showing at The clock occupies one window, a glance the month, the day of the month, and day of week, and is so constructed that the long and short months, and even the extra day in February of Leap Year are correctly indicated. Mr. Benson has placed in a third window a wind dial, fitted with a pointer, which indicates on the compass the direction of the wind. The three dials are illuminated

RECENTLY, in removing a sand bank contiguous to the Ouse, a few miles north of York, a deposit of stone and flint axes, knives, flakes, &c., was found at about 10ft. deep in undisturbed sand, and beneath several unbroken layers of leamy clay. A party o archeologists, among whom were Canon Greenwell, of Durham, the Rev. J. Robertson of Appleton, and Mr. George Slater, of Malton, have visited the place Mr. George Slater, of Malton, have visited the place and made a thorough examination. From the survey and from the evidence collected the implements seem to have come from beneath several feet of apparently undisturbed gravel sand, but were generally thought not to be of the same age as the sandbeds. The thing is a puzzle for geologists and archæologists both.

The bronze doors designed, one for the entrance to the University States House of Representatives, and

to the United States House of Representatives, and the other for one of the doorways of the Senate hamber at Washington, and which had their inception some fifteen years ago, are now in their places, and receiving the finishing touches. Each door weighs entire 8,000lb., and its casing 6,000lb. more, so that the total weight of the bronz, work in each door is 14,000lb. The designs upon the panels illustrate the history of the discovery of America by Columbus, and sprang from the genius of Crawford and Rogers, the former of whom died before his portion of the work was quite completed. The sum total of the cost to the American Government will be about 50.000 dollars.

THE Metropolitan Board of Works has ordered THE Metropolitan Board of Works has ordered that the line of thoroughfare extending westward from Cavendish-square to the intersection of Dukestreet, and now known as Wigmore-street and Edwards-street, be named Wigmore-street throughout. That the subnames in Clapham-road and Clapham-rise be abolished, and that the whole line of thoroughfare from Kennington Park-road to Highstreet, Clapham, be called Clapham-road. The Board has also issued a general order directing that in every case where plans of new streets are approved, every case where plans of new streets are approved, a condition be attached that the name of each street, as approved by the Board, be affixed on posts at both ends of such proposed new street, until the houses are built, when the name shall be affixed according

THE MANUPACTURE OF WATCHES AND CLOCKS. THE MANUFACTURE OF WATCHES AND CLOCKS.

A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 38 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices and no one should make a proclass. tion of the various kinds of watches and clocks, with their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, who holds the appointment to the Prince of Wales, sends this namphlet to any address on receipt of two postthis pamphlet to any address on receipt of two postage stamps, and we cannot too strongly recommend it to the notice of the intending purchaser.—[ADVI.]

1992 G. OWEN, Islington. Chess men. Dated June 20

1863.

The inventor constructs his chess board and chess men in either of the two following ways, that is to say, he inserts a magnet or magnets in each square of the chess board, and attaches a disc of thin sheet iron to the base of each pawn and piece, or he inserts a magnet of suitable form in the base of each pawn and piece, and into or upon each square of the chess board he fixes a button or disc of iron. By this contrivance the pawns and pieces are held securely in their places upon the board.—Patent abandoned.

doned.

193 W. UMPHERSTON, Loanhead, Edinburgh. Steam engines. Dated June 20, 1868.

The patentee claims the arrangement of the double motion lever in connection with the auxiliary cut-off valve and governor slide, and of the opener, and of the spring, weight, or other means used for giving the clothing motion, and of the stopper, so as to produce the effects described, and the regulating by means of these the speed of steam engines, so as to secure an almost uniform rate of speed notwithstanding variations of burden, or of steam pressure. The details of the invention are voluminous.—Patent completed.

1994 G. Midwood, Manchester. Treatment of certain reasts yarms or threads. Dated June 20, 1868.

The patentee first opens or breaks up the coloured cotton waste by means of the ordinary well-known machinery hitherto used for opening or breaking up grey waste; and he afterwards mixes the coloured fibres thus obtained with cotton, linen, or other fibres of a superior quality to give them greater strength, and he then cards and spins the fibres thus mixed by means of the ordinary carding and spinning machinery, thus reforming them into yarn or thread which is wound into the form of cops, or on spools for the shuttle of the loom, or for other similar use. Second, he applies the ecoloured or mixed yarn or thread thus reproduced or remade from coloured cleaning waste, to the manufacture of woven fabrics in the ordinary loom in which he employs it principally in the form of west, interweaving it with a stronger warp for the purpose of giving strength to the fabric.—Patent completed.

1995 G. Richardson, Whitefield, Lancashire. Looms.

1995 G. RICHARDSON, Whitefield, Lancashire. L.

1995 G. RICHARDSON, Whitelield, Lancasnire. Looms. Dated June 20, 1668.

The patentee claims the peculiar combination of mechanism consisting of an endless chain of adjustable bows. worked intermittently in connection with the vertical notched bars or treadles, and reciprocating levers actuated by a cam, substantially in the manner and for the purpose, set forth and illustrated.—Patent completed.

set forth and illustrated.—Patent completed.

1996 A. A. COMMON, South Bank, Regent's-park.

Manufacture of stench traps for drains. Dated June 20, 1868.

These improvements do not apply to the manufacture of what is commonly known as the bell trap, but to traps formed by a receiving basin or bowl in the centre of the body, into which bowl dips a piece supported on the upper rim of the said body. The inventor proposes to cast the body outlet and dip of one piece, and to join the bowl to the body in the casting of this latter.—Patent abandoned.

1997 H. W. HART, Bayswater. Urns for containing teac. Dated June 20, 1868.

1997 H. W. HART, Expansion.

Ac. Dated June 20, 1868.

This invention consists in constructing such tea pots, coffee pots, and jugs, vessels, or urns for containing cocoa, chocolate, and such like beverages, with a double casing, the space between the inner and outer casing being filled with a material that is a good non-conductor of heat, such as felt, so that the heat of the beverage shall be prevented from being communicated to the outer casing, and thus lost by radiation therefrom. The inventor prefers, also, to make the cover of the tea pot or other vessel, as also the spout, with a similar double casing.—Patent abandoned.

1000 I Hadden City Flour Mills, London. Apparatus

1998 J. HADLEY, City Flour Mills, London. Apparatus for cleaning and decorticating wheat. Dated June 20, 1868. This invention relates to the cleaning and decorticating

of wheat by subjecting it to friction between stationary and rotating yielding and elastic surfaces. Before submitting the wheat to the decorticating operation the patentee first screens and winnows it by any approved apparatus, and he then passes it between friction surfaces.—Patent completed.

1999 W. R. G. WRIGHT, Glasgow. Propelling of thiss, &c. Dated June 20, 1868.

This invention consists, essentially, in propelling ships or vessels by a new or improved hydraulic propeller, and a reaction hydraulic wheel or motor for actuating the same, driven by the pressure and quantity of water forced through the said screw and wheel for the purpose by any of the usual means and apparatus heretofors in use for forcing water through pipes or conduits, and which compound propeller thus actuated propels the ship or vessel by the combined action of the screw acting direct on the water to be displaced, as usual, by preference, at the stern of the ship, and the reactionary force of the actuating or escaping water of the reaction wheel, acting on the principle of hydraulic jet propellers.—Patent abandoned.

2000 C. H. MURRAY (Loman-street, Southwark. Derice of the state of the state

principle of hydraulic jet propellers.—Patent abandoned. 2000 C. H. MURRAY, Loman-street, Southwark. Dericg for uniting and securing the ends of scraps, &c. Dated June 20, 1868.

This invention consists, chiefly, in the combination of a slotted piece or frame with a wedge, the two ends of a strap being inserted into the aperture in the said piece, and the wedge being placed between the said two ends in such a manner that the greater the strain tending to separate them the more firmly the wedge will bind and secure them.—Patent completed.

2001 J. BONNAL (Grapham, Threating marking Date).

2001 J. BONNALL, Grantham. Thrashing machines. Dated

separate them the more firmly the wedge will bind and secure them.—Patent completed.

2001 J. BONNALL, Grantham. Thrashing machines. Dated June 20, 1868.

This invention relates, first, to a novel construction of the seats or plummer blocks and bearings of thrashing and other machines, whereby they are rendered self-adjusting, and allow any ordinary deflection of the shafts or axles working in them. The invention relates, second, to means of attaching the connecting rods to the shoes or dressing apparatus, and the hangers or vibrating links to the straw shakers. The invention relates, third, to the application of sack elevators to the before-mentioned machines. The invention relates, fourth, to improvements in straw elevators to be used in connection with the before-mentioned thrashing machines. The details of the invention are voluminous.—Patent completed.

2002 J. Shelmerdine, W. Walker, and H. Holt, Manchester. Valve gear for steam and other motice engines. Dated June 20, 1868.

This invention relates to that class of valves where one valve is worked by an eccentric or other means to regulate the admission and exhaustion of the steam, and another valve is applied to the first named or primary valve to be moved with it by the friction caused by the prossure of the steam upon the second valve, this second or supplementary valve acting when its movements are stopped to cut off the supply of steam to the primary valve, which then slides under it, and the object of the invention is an improved arrangement and combination of mechanism to stop the movements of the supplementary valve at different parts of its traverse, so as to cut off the supply of steam to the cylinder at a different part of the stroke of the piston, and thus regulate the expansive working of the steam, this being done by adjusting the valve gear by hand, or by connecting it with a suitable governor, which will vary the time of cutting off the steam according to its pressure, or to the load upon the engine, so as to keep the speed uniform, the fu

the lever.—Patent completed.

2003 J. BAYLISS, Cannon-street. Wrought-iron hurdles, gates, and fencing. Dated June 20, 1868.

This invention appertains to the description of hurdles, gates, or fencing made with rectangular standards, and rectangular rails, and round or oval horizontal or vertical rails, and consists in cutting the rails off to the length required, and in removing as much of the round part of the iron as to form a rectangular tenon and shoulders; and by punching corresponding holes in the standards or bottom or other rail as may be required for receiving the rectangular tenon so formed, they simply require to be riveted or spread over on the outer or extreme ends to complete the hurdle, gate, or fencing to which this mode of manufacture may be applied.—Patent abandoned.

2004 S. BOWEN, C. GLOVER, R. H. DAVIS, T. STANDFORD.

riveted or spread over on the outer or extreme ends to complete the hurdle, gate, or fencing to which this mode of manufacture may be applied.—Patent abandoned.

2004 S. Bowen, C. Glover, R. H. Davis, T. Standford, and T. Scott, Birmingham, and A. M. Ball, E. Silellon, W. Farmer, L. Maskall, E. Coburn, and J. C. Cole. Smethwick, Stafford, Improvements in machinery for cutting or worming screws. Dated June 20, 1868.

This invention consists, first, in arranging a pair of screwing dies, so that they may be opened by self-acting mechanism, constructed as described, the said dies forming what is commonly called a solid die when in the act of cutting or worming free screwing is completed, the opening of the dies releasing the screw. The opening of the dies releasing the screw. The opening of the dies is effected by hand. The invention consists, second, in the use of a quick threaded screw or inclined plane in the front end of the screwing spindle for starting the blank into the screwing dies. The invention consists, third, in fixing in a diagonal position the rods by which the saddle carrying the screwing dies is supported. By this arrangement the said rods are out of the way of the attendant, and afford great facility for arranging the dies. It consists, fourth, in fixing the screwing machine on a hollow pillar or column, in such a manner that the pillar or column may be used for supporting an oll basin, the interior of the pillar or column containing boxes for storing tools or for other purposes; and, lastly, in the general arrangement of the screwing dies, the starting screw, or plane, and the diagonal rods for supporting the saddle carrying the dies hereinbefore referred to in connection with each other, and in combination with the hollow pillar or column hereinbefore referred to.—Patent completed.

2005 V. DE STAINES, Shepperton Villas, London, Boat, &c. Dated June 22, 1868.

First, for the construction in the contrivance of a

longitudinal channel or passage under the boat or vessel by means of two flauches or cheeks, descending one on each side of the vessel, and so confining the water as to give it a greater power of resistance in supporting the vessel, which at a certain velocity will gilde with very little friction on the top of this liquid rail. Second, for the propulsion, in placing the paddle-white, screw, or other propelling power directly in front and in a line with the above channel, so that all the agitation communicated to the water passing under the boat shall contribute to its support and progress as well as any air or gas thereby introduced.—Patent abandoned.

2006 R. and W. K. Austin, Glasgow. Rolary engine.

2006 R. and W. K. AUSTIN, Glasgow. Rotary engines and pumps. Dated June 22, 1868. This invention is not described apart from the drawings

Patent completed.

1868.

We cannot here give space to the voluminous details of this invention.—Patent abandoned.

this invention.—Patent abandoned.

2003 E. T. HUGHES, Chancery-lane. Machines for polishing needles. (A communication). Dated June 22, 1868.
This invention relates to improvements in the process of finishing needles after they have been tempered, and consists, first, in the peculiar manner of scouring the needles, whereby the roll or bag is kept in constant revolution, and, second, in mechanism for polishing the needles after they have been scoured. The details of the invention are voluminous.—Patent completed.

are voluminous.—Patent completed.

2009 E. T. HUGHES, Chancery-lane. Metallic cartridges.
(A communication). Dated June 22, 1868.

This invention relates to improvements in metallic cartridges, and especially those designed repeating or magazine arms, the object being threefold:—First, to produce a cartridge that shall be less liable to accidental explosion, both in handling and also in the magazine of the gun. Second, to so strengthen the base or head as to prevent the breaking or pulling off of the flange or head; and, third, to produce a central-fire cartridge, so constructed as to act as a cushion for the purpose of relieving the breech pin more or less from the sudden shock or strain caused by the explosion of the charge. The invention is not fully described apart from the drawings.—Patent completed.

pleted,
2010 W. E. Gedge. Wellington-street, Strand. Means of indicating whether the doors of railway carriages are securely fastened or simply closed. (A communication). Dated June 22, 1868.

It is proposed to indicate the position of the handle on the outside by the words "open," or "closed," or "fastened," placed within the carriage. A fixed plate with, say, a red ground will have inscribed upon it the word "open," and will be visible so long as the door is not completely fastened. A movable plate with, say, a blue ground fixed on the spindle of the handle, and hidden within the panel of the door, comes over the fixed plate when the handle is turned from the exterior to fasten the door. This blue plate will bear an inscription to the effect that the door is fastened.—Patent abandoned.

2011 W. A. GILBEE. South-street, Finsbury. \*Manufacture\*

-Patent abanconed.

2011 W. A. GILBEE, South-street, Finsbury, Manufacture of cards for carding. Dated June 22, 1868.

This invention consists in an improved construction of machine or apparatus for making cards for carding, by which a greater amount of product is obtained than by the ordinary machinery, a whole row of teeth being made and inserted in a sheet or band of leather or india-rubber at each revolution of the driving shaft of the machine.—Patent completed.

Patent completed.

2012 M. Gray, Highbury-hill, near London, and M. Grisson, Silvertown, Essex. Coating or covering electric conductors. Dated June 22, 1868.

The object of the first part of this invention is so to arrange and construct the dies or die plate with respect to the inozzles as to be able to effect the required adjustment of any particular nozzle or dio with facility, and while the covering operation is proceeding. A further improvement in coating electric conductors consists in treating the wires which are to be covered with guita-percha with a preparatory coating for facilitating the adhesion of the guita-percha to the wire. This coating consists of a compound composed of gum balats, resin, oil, and pitch.—Patent completed.

2013 A. M. CLARK. Chancerv-lane. Apparatus for wind-

of guin balata, resin, oil, and pitch.—Patent completed, 2013 A. M. Clark, Chancery-lane. Apparatus for winding thread. (A communication). Dated June 22, 1868.

These improvements relate to the application of a guide or conductor for guiding the thread in an even and regular manner throughout the length of the bobbin or spool, so as to cause it to be wound evenly thereon in successive layers. This thread guide has to and fro motion imparted by means of a cam, eccentric, or other mechanical equivalent, also forming part of the invention.—Patent completed.

completed.

2014 C. Whitehouse. Bridgtown, near Cannock, Stafford. Mill bills and picks for dressing millstones. Dated June 22, 1868.

The patentee claims making the head or frame of the bill or pick of a fixed part, a movable part, and making the acting ends of the said head or frame, separate from the head or frame, the said movable and fixed parts of the head or frame, and the acting ends being constructed, and the acting ends fixed, gripped, and held in the head or frame for use, substantially as described and illustrated.—Patent completed.

-Patent completed.

2015 G. TAYLOR, Bradford. Boots and shoes. Dated June 22, 1868.

This invention consists in making boots and shoes with caoutchouc soles having nipples or projections on their under surface; the inner sole is perforated; and there is a flap valve opening downwards, whereby ventilation to the foot is secured, and great flexibility is imparted to the sole.—Patent completed.

sole.—Patent completed.

2016 J. and J. HAYES, Elton, Huntingdon. Machinery
for actuating strate shakers. Dated June 22, 1863.

This invention relates to a poculiar mechanical arrangement for transmitting a rapid vibratory motion to the
shaker bars of straw shakers, and to the process or riddles
of vibratory screening apparatus, and is particularly applicable to the machinery for shaking, riddling, raising,
and delivering straw and other like agricultural produce,
for which the inventors obtained letters patent, dated
April 16, 1866 (No. 1072).—Patent abandoned.

2017 J. H. JOHNSON, Lincoln's Inn-fields. Red colour. (A communication). Dated June 22, 1868.

This invention relates to the production of a red colour.

from aniline or saits of aniline, and consists in subjecting aniline or saits of the same to the action of a nitrite, by aniline or saits of the same to the action of a nitrite, by a consist of the same to the action of a nitrite, by a contained in a three before-mentioned substances being contained in a suitable ressel or apparatus, heat is to be applied until suitable reselved and the crude mass then the desired colour is produced, and the crude mass then resulting is to be subjected to the action of water, and refer the removal of the soluble saits, the colouring matter site the removal of the soluble saits, the colouring matter is to be dissolved in a solvent of the same, such, for example, as boiling water, or a dilute solution of acid, for example, as boiling water, or a dilute solution of acid, for example, as boiling water, or a dilute solution of acid, and manner well understood by manufacturers of aniline colours.—Patent abandoned.

2018 Lieutenant C. H. M. Downing, Gloncester-terrace,

This is forced forward into the flue combining of air. This is forced forward into the flue combining with the waste products of combustion, and is caused to with the waste products of combustion, and is caused to point.—Patent abandoned.

2041 R. ELSDON, Brockham, Surrey. Burning lime and

point.—Patent abandoned.

2041 R. Elsdon, Brockham, Surrey. Burning lime and cement. Dated June 24, 1868.

In calcining lime and cement the inventor employs a rotating furnace. He constructs the furnace of a tubular form; it is closed at one end, and at the other it is tapered form; it is closed at one end, and at the other it is tapered transverse section of the tube. This furnace is mounted transverse section of the tube. This furnace is mounted in a frame in such manner that it may be rotated about its longitudinal axis; there is a stud or axis fixed at the its longitudinal axis; there is a stud or axis fixed at the in a bearing on the frame. At the other end of the frame in a bearing on the frame. At the other end of the frame is understood in the mouth. The frame also furnace immediately behind the mouth. The frame also furnace immediately its length, so as not to interfere with its intermediate of its length, so as not to interfere with intermediate of its length, so as not to interfere with its intermediate. There is much other detail.—Patent abandoned.

rotation. There is much other detail.—Patent abandoned.

2042 E. Mucklow. Bury. Lancashire. Utilizing refuse
tanning matters for dyeing purposes. Dated June 25, 186s.
This invention relates to utilizing the waste or refuse
material employed by tanners, such as the spent oak,
material employed by tanners, such as the spent oak,
myrabolams, dividivit, gambler, and all similar materials,
myrabolams, dividivit, gambler, and all similar materials,
after the same has been used in tanning hides and skins.

—Patent completed.

2043 J. Bridge. Barrow. Lancashire.

Patent completed.

2013 J. Brider, Barrow, Lancashire. Constructing ingot noulds. Dated June 25, 1868.

An extension of time for completing this patent having seen petitioned for and granted, the documents relating to the invention cannot at present be seen.

to the invention cannot at present be seer.

2044 J. Jack, Liverpool. Auxiliary scree propellers to sating ships. Dated June 25, 1868.

The object of this invention is to provide sailing ships with auxiliary screw propellers capable of propelling with auxiliary screw propellers capable of propelling with auxiliary screw propellers capable of propelling them during calms and adverse light winds; and at other times such propellers are so arranged, and the ships to times such propellers are so arranged, and the ships to which they are fitted so constructed, that the screw, with which they are fitted so constructed, that the screw, with which they are fitted so constructed, that the screw, with our being removed from the shaft, can, when not required for propelling purposes, be housed in a recess formed for propelling purposes, be housed as aforesaid, the working space. When the screw is housed as aforesaid, the working space when the screw is housed as aforesaid, the working space when the screw is housed as aforesaid, the working space when the screw is housed as aforesaid, the working space when the screw is housed as aforesaid, the working space when the screw is housed as aforesaid, the working space.

Patent completed.

2045 E. LEYER, Denton, Lancashire. Coating of woren fabrics. Dated June 25, 1868.

This invention consists in the application and use of paper pulp or fibrous pulp to the surfaces of woven fabrics, paper pulp or fibrous pulp to the surfaces of woven fabrics, and applied thereto in a liquid or pulp-like state, so as to enter and fill the interstices between the warp and weft.—

Patent abandoned

2046 A. D. AULTON, Walsall, Stafford. Sewing machines. Dated June 25, 1868. Sewing machines have hitherto been driven by means

of a foot treadle, hand crank, or, occasionally, by steam power. The object of this invention is to provide another motive power, better adapted for the purpose for which it is intended to be applied. The motive power the inventor employs, consists, substantially, of a coiled spring which is wound round an axis.—Patent abandoned.

inventor employs, consists, substantially, of a colled spring which is wound round an axis.—Patent abandoned.

2047 J. G. GARRARD, Harlow. Rick cloths. Dated June 25, 1868.

The patentee claims the adaptation and application to ricks of a cloth composed of canvas, felt, or other suitable material with an opening, by means of which it can be folded in, so as to make it fit the tops of ricks of different sizes, as described.—Patent completed.

2048 Rev. H. Highton, M.A., Brighton. Manufacture of artificial stone or slate. Dated June 25, 1868.

The patentee is aware that sulphate of alumina and chloride of barmim, and other salts mutually decomposing each other, have been used for hardening the surfaces of stone, and salts of iron, and other metals, for dyeing artical stone, and, therefore, he only claims the use of these methods of colouring when applied to blocks of artificial stone or slate, made as described.—Patent completed.

2049 G. T. Boustield, Briston. Fivearms and cartridges. (A communication). Dated June 25, 1868.

The patentee claims the application to cartridges of cupped discs of cloth, felt, or other similar material, in the manner described, such cartridges being made of a diameter exactly equal to that of the bore of the gun, as and for the purposes described. Second, the construction and application of extraction with or without a spring or lever for throwing out the cartridge case, arranged substantially in the manner shown and described. Third, modifying existing cartridges, in the manner described, to enable the cases to be extracted after firing. Fourth, in constructing paper cartidges so as to retain the bullet without tying; as also the peculiar mode of filling such cartridges, all as described.—Fifth, the improvements in gun actions, arranged and operating substantially in the manner shown and described.—Patent completed.

2050 J. Hine, Occkermouth. Cutting or dressing millistones.

gan actions, arranged and operating substantially in the manner shown and described.—Parent completed.

2050 J. Hine, Cockermouth. Cutting or dressing millstones. Dated June 26, 1868.

This invention relates to apparatus for facilitating the cutting or dressing of millstones by hand by means of diamonds or other hard stones or cutters. The apparatus consists of parallel bars connected together by links in the manner of a parallel ruler of suitable size, through one bar of which passes a screw working in a screw-nut fixed thereon ina central position. The one end of the said screw is received in a longitudinal groove made in the inside face of the other or movable bar, the other or projecting end of the screw being provided with a thumbhead to facilitate turning. Metal plates are also fixed on the inner face of the movable bar taking into a neck formed on the end of the screw in either direction; the movable bar is moved towards or away from the fixed one, in the manner of a parallel ruler. The fixed bar is provided with a stop or projection at either end, which bear against the furrow in the stone on the side furthest from the surface to be cut, by means of which the bar is held steady when in use. These stops are provided on both sides, to enable the apparatus to be reversed when required. The cutting tool consists of a diamond or other hard stone mounted in a suitable holder, and recessed into a metal block somewhat resembling a plane, the diamond cutters or cutters projecting from the under face thereof. The block, which is provided with a handle, is passed over the surface of the stone in the manner of a plane, being guided in its motion by the movable bar before mentioned, against the face of which it bears. After each passage of the cutting tool the movable bar is advanced a cortain distance by turning the screw, and the tool again moved across the surface of the stone as before, thus producing parallel lines or cuts of great regularity. The parallel apparatus is transferred to each furrow successively to

sively to complete the cutting or dressing of the surface.—Patient completed.

2051 C. Hastings, J. Briggs, and J. Law, Bradford. Apparatus for finishing yarns. Dated June 26, 1868.

The object of this invention is to remove the impurities from and clongate and straighten worsted and other yarn either after or before it has been singed or otherwise prepared. In performing this invention the patentees cause the yarn to pass through a trough containing a hot solution of soap and water, or a hot or cold solution of either ingredients, to prepare the yarn, which, before it passes into the trough, is operated upon by a brush or other cquivalent to remove the loose impurities. The trough is provided with one or more guide rails to give friction to the yarn, and with a heating apparatus to keep the solution warm, and after the yarn has passed through the solution warm, and after the yarn has passed through the solution it is wound on to bobbins while still wet; by this means the yarn is considerably improved in appearance, and is in better condition for the loom or for any other subsequent operation.—Patent completed.

2052 C. D. Abel, Southampton-buildings, Chancery-lane.

2052 C. D. ABEL, Southampton-buildings, Chancery-lane Apparatus for cleansing or washing bottles. (A communication). Dated June 26, 1868.

This invention has reference to new or improved

This invention has reference to new or improved machinery or apparatus for simultaneously and effectually cleansing both the interior and exterior of bottles. We cannot here quote the details of the invention.—Patent abandoned.

2053 T. DODD, Crumlin, Monmouth. Arrangements for overing and uncovering railway trucks, &c. Dated June 26,

1868.
This invention has for its object the construction of railway trucks and waggons with readily movable tops, roofs, or covers, each such top, roof, or cover being supported on a roller fixed upon the truck or waggon, which movable top, roof, or cover, when required to be used for protecting the inside or contents of the truck or waggon, is rolled on or covers the same by turning the said roller so as to unroll or unfold the same. The invention is not described apart from the drawings.—Patent completed.

2054 T. Burke, Liverpool. Folding chairs. Dated June 26,

1868.

The object of the first part of this invention is to furnish chairs constructed with ordinary or convenient diagonal cross legs and flexible or other seats, with folding backs, each such back being free to be moved so as to serve at pleasure as a back rest on either of two sides of the seat. For this purpose the patentee makes the said folding back of two side-frame pleces, and a transverse rail, and con-

nects the former by pin or other joints to the two outer diagonal cross legs at points below the centres which connect the cross legs. The said folding back is made long enough to rise above the seat any desired distance, and it can, as aforesaid, be moved from one side to the other at will, stops on the sides of the cross rails being provided to prevent it folding over too far, and to serve as a support. This chair is specially suitable for use on board ship; it is also serviceable for general use. The second part of the invention relates to that class of folding chair constructed with diagonal cross legs, a seat hinged to the back rail, and a downwards and forwards folding back, and consists as means for supporting the back frame, and, consequently, strengtheving the chair, as a whole of a transverse stop-piece affixed to the two back legs or near the top thereof at a point above the joints which connect the back to the legs. Chairs of this description fold up in very small space, and by being strengthened as described are rendered serviceable and durable.—Patent completed. completed.

2055 T. WINDER, Liverpool. Marine chain stoppers. Dated June 26, 1868.

Dated June 26, 1868.

This invention relates to improvements in the construction of that class of marine chain stoppers known as elastic stoppers, in consequence of certain parts thereof yielding or giving when the chain or cable is drawn "taut," and consists, first, in the employment of one or more springs of a novel construction placed between the fixed and movable frames. These springs are made of india-rubber or other elastic gum, and each one in form resembles the frastrum of a hollow cone. Second, in employing on the movable frame an eccentric and lever to raise and lower the "catch bit."—Patent completed.

2058 R. CLOUGH. Keighley, York, Loons. Dated

2056 R. CLOUGH, Keighley, York. Looms. June 26, 1868

2056 R. CLOUGH, Keighley, York. Looms. Dated June 26, 1868.

This invention relates to means of working healds or heddles of looms employed for weaving fabrics, technically known as "lastings" and "serge de berries," and the object is to enable the weights employed for lifting the said healds or heddles to be regulated or adjusted in their weight or pressure according to the sort or quality of cloth to be woren without having the said weights to change, as heretofore. For this purpose the patentee employs a series of ordinary jack rods and levers (instead of the bowls or pulleys and cords now used), to attach the top parts of the healds to the bottoms being attached to levers operated by treading tappets as usual, and he employs a series of levers, each being hinged at one end to the loom end frame, and the other attached by cord or rod to a lever fixed on one of the jack rods. The weights are attached to these levers and are capable of being moved thereon, as required, so as to regulate or adjust their pressure or action on the healds in lifting them.—Patent completed.

2057 S. S. MAURICE, Monkwell-street, Wood-street,

completed.

2057 S. S. MAURICE, Monkwell-street, Wood-street, London. Fastening for neckties, &c. Dated June 26, 1863.

This invention consists of a roller or piece shaped as described, mounted and working eccentrically, in such manner that, when worked in one direction, it exerts pressure on and retains in place the tongue, slide, band, or movable piece of the necktie or other article to which the said fastening is applied, and which tongue, slide, or movable piece it releases when worked in the other direction.—Patent completed.

2058 J. TAYLOR, Castle Iron Works, Staleybridge, Cheshire. Opening, cleaning, and preparing cotton, &c. Dated June 26, 1868.
This invention consists in arranging or combining two machines for opening, cleaning, and preparing cotton and other fibrous materials, of that class in which the material is fed and discharged from the same side of the machine, so that the material fed to and operated upon by one machine will be conveyed by mechanism and fed to the other machine, while the two machines may be so arranged as to be used singly if required.—Patent abandoned.

2059 A. THOMSON, Southampton. Water-closets. Dated June 26, 1868.

This invention consists in constructing water-closets in which a disc valve which closes the bottom of the pan is moved on one side clear of the pan, when a handle in the seat, or in other position is moved in a curved slot or otherwise, while, by the same movement, a valve for admitting a supply of water to the flush pipe is opened and the pan is thus flushed.—Patent completed.

pipe is opened and the pan is thus nusned.—ratent completed.

2000 T. H. HOLMES, Gravesend, Kent. Electro-magnetic and magneto-electric machines. Dated June 26, 1868.
This invention consists, first, of a new form of electro-magnet composed of two discs, both of which are hollowed on one side and rounded or made convex on the other; from the edges of these discs project arms which are placed at such distances apart that, when the two discs are brought with their concave sides facing and near to each other, the arms will not be too close. These arms are curved or so applied to the discs that, when the latter are fixed on a shaft, and at a certain distance, they form a ring with poles alternately north and south, and are in the same plane. These electro-magnets may be manufactured of steel or wrought or cast iron, or of any mixtures or combinations of metals susceptible of being converted into magnets. The invention consists, second, of certain new forms of holices or coils, the cores of which are made of two pieces of half-round iron, or of two pieces of iron having a flat side.—Patent completed.

2061 L. Thomas, Leadenhall-street. Apparatus to be

pieces of iron having a flat side.—Patent completed.

2061 L. Thomas, Leadenhall-street. Apparatus to be used along shore for the distillation of pure water from salt water. Dated Juno 26, 1863.

This invention consists, first, in so constructing condensers that they can be placed (and the so placing of them) right into or under the water of the sea or river or lake where they may be used. Second, in disponsing with the outer shell or casing of condensers; and, third, using by this peculiar arrangement of the steam pressure to bortel the distilled water into a tank or reservoir ashore.—Patent completed.

Patent completed.

2062 A. H. Brandon, Paris. Metallic cartridge shells and heads. (A communication). Dated June 26, 1868.

This invention consists in making a cast or stuck-up cartridge shell and head in one piece with pure tin, or an alloy of tin and lead, or other metals, or lead alone, the said cartridge case baving the usual priming tube formed in it or not, and having a plate of metal surrounding the priming tube or without the said plate. The principle of the invention is the making a cartridge case and head with the above mentioned metal or mixture of metals at one

operation either by striking or casting.

doned.

2063 T. C. BLANCHFLOWER, Great Yarmouth. Packing preserved meats and fruits for sale. Dated June 26, 1868.

This invention consists in using a disc of glazed earthenware or glass of such size and shape that it shall fit the pot or vessel that is to receive the animal or regetable preserve, and the disc the patentee places and allows to rest upon the preserve, by which means the air will be effectually excluded therefrom.—Patent completed.

2064 A. H. Brandon, Paris. Machinery for spinning hamp, &c. (A communication). Dated June 26, 1868.

This invention is not described apart from the drawings.—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT.

# WAYGOOD'S PATENT DONKEY PUMP

## OR IMPROVED BOILER FEEDER AND INJECTOR.

The numerous articles of this kind now offered proves their great utility. Amongst the various competitors for public patronage, we claim many advantages over most of the others, for the following reasons:—The first is its extreme simplicity; next, it is a well-known fact that steam pumps with small flywheels must of necessity act very rapidly, in order to obtain a sufficient amount of centrifugal force in the wheels to keep themselves going; this rapidity prevents them from properly filling the barrel; the plunger thus acts o. a partial vacuum, which tends to loss of power and self destruction. Neither with so shout a stroke can water be brought from any depth. The improved one which we now offer, and which is represented in the sketch, has no flywheel, and has a stroke of fully double the usual length; this enables them to bring the water up 20ft, if required. It works most effectively at from 30 to 60 strokes per minute; the barrel thus fills at every stroke, and delivers its charge into the boiler with great regularity, under any pressure, from 51b, to the inch up to 150. The small quantity of steam it consumes is surprizing. Any Pump not found to answer the description above given can be returned after a month's trial.

Any number of Testimonials can be given. They have been adopted at the Woolwich Arsenal, where they give perfect satisfaction.

## MECHANICS' MAGAZINE.

LONDON: FRIDAY, JANUARY 15, 1869.

#### SYSTEMS OF DRAINAGE.

WHATEVER success may have attended the partial introduction of the "dry earth" method in isolated districts and pe culiar localities, it cannot be included in the category of drainage and sewerage systems. Its advocates appear now to be convinced of the utter futility of endeavouring to extend its sphere of application beyond its legitimate limits. At one time they entertained the preposterous and extravagant notion of adapting the principle to the requirements of large towns, and even metropolitan cities. Gradually, these unfounded expectations have subsided. The numerous attempts undertaken with the view of securing the co-operation and influence of local boards have proved entire failures, and while there is no doubt of the value of the "dry earth" principle in the case of barracks, hospitals, outlying districts, and localities where no drainage exists, there is equally not the slightest doubt that it is not, and never can be, rendered available for the exigencies of a large city. Independently of the re-pugnance that people of English tastes, habits, and proclivities would unquestionably manifest towards the using of the earth, its subsequent desiccation, and ultimate re-uti-lization, we maintain that the principle per se is defective and incomplete when regarded from a point of view sufficiently comprehensive to embrace every instance that might present itself. That dry earth is a most effectual deodorizer will be universally admitted, and if every individual farmed his own small portion of land, and sat under his own vine and his own fig tree, it would be impossible to devise a more simple or more ready method of utilizing sewage matter. But as this primitive phase of existence is not in accordance with the progress of European civilization, means that are admirably adapted for promoting the same end under one régime are not admissible under the regulations of another. The dry earth method bears some resemblance to the "separate" system, which we shall consider presently, insomuch as it makes no provision for the removal of any of the house or kitchen refuse, or of the storm and surface water.

Omitting all further consideration of this imperfect and incomplete method, we will now investigate the three bona fide systems, and briefly examine into their relative capabilities and advantages for effecting the desired result. They may be classed under the heads of the single, the double, and the mixed systems, and, in addition, are all included under the general term of "sewage by water carriage," in contradistinction to the dry method to which we alluded at the commencement of the present article. The single or separate system is that in which the sewers are considered strictly as such and They serve as channels for the conveyance of sewage matter alone; and no other refuse, fluid or solid, is permitted to form part of their contents. The double system is the most comprehensive of the three, and the sewers take everything they can get in the shape of sewage matter, house drainage, rain, and surface water, and, in fact, everything that is not too large to pass the grat-ings and traps of the drains. Under the third classification, or the mixed system, we have a compromise between the other. A certain portion of the surface water and street drainage passes into the sewers, while the re-mainder is carried off by other channels, and frequently by open watercourses,

gation is the only efficient method of utilizing town sewage is now a truism, incontestably established by the results of actual experience and agricultural experiments. quently, the whole question turns upon the relative advantages of permitting the surface drainage and storm waters to form a portion of the contents of the channels which serve for the transport of the sewage matter. consideration of this point may be regarded as of a twofold character—the one concerns the immediate and rapid removal of the sewage from the vicinity of human dwellings; the other its subsequent utilization. The first of these is unquestionably the more important, and deserves the greatest attention. It is the sine qua non of every sanitary measure and precaution undertaken for the wel-fare of any district, urban or rural. The fare of any district, urban or rural. second is likewise of considerable and grave interest, but nevertheless in some degree subsidiary to or contingent upon the first. It is upon this rock that all the advocates for the dry earth principle have split, when they endeavoured to apply it upon an extensive scale. They make the conversion of the sewage into manure and its utilization the primary consideration, and its removal from the habitations of men the secondary; thus virtually putting the cart before the horse. plan of constructing, as is necessary in the "single" system. separate surface and the sewage drainage, it would be the enormous and unwarrantable expense that must of necessity be incurred. Imagine London with a duplicate system of "metropolitan drainage"! Again, what is the object to be gained by the adoption of separate channels? A certain quantity of water is absolutely necessary to act as the transporting power for the sewage, and, in cases where the fall is unavoidably very slight, artificial means of flushing have to be resorted to. Where can this power be so conveniently and cheaply obtained as from the surface drainage? We shall not allude to the unnedrainage? cessary expense that must attend the construction of storage reservoirs and settling tanks, -and all for what? To deduct from the sewage channels a portion of their contents. The only other argument against running off the surface drainage in the sewage channel is that it dilutes and deteriorates the sewage itself, thereby rendering it less suitable for irrigation. This argument is more specious than real, and experience has not confirmed its validity. It, besides, omits the prominent fact that the water in sewage is frequently of as much value as the fertilizing ingredients, especially on very dry land, and during a season like the past. All solid manures artificially prepared from sewage and applied to the land, have resulted in miserable failure, and utterly disappointed the hopes entertained by their advocates with respect to both the anticipated sale and agricultural value. results of the application of the metropolitan sewage, taken direct from the main sewer, to every description of green and cereal crops upon the farm at Barking, is an indisputable proof of its fertilizing powers. The success of sewage irrigation over every other method of manuring the ground is due to the fact that it combines the two elements of fertilization and irrigation. Each of these, exemplified by simple farm manure and by water, is itself efficacious to a certain extent, and it is therefore no wonder that when combined they should endue the land to which they are applied with unexampled fecundity.

The mixed system is hardly deserving of consideration, as it is simply an entrenchment upon the features of the other two, without possessing any distinct ones of its own. It is open to the objections urged against the single system, and is endorsed

neutral ground upon which the advocates of either of the other two systems might be reconciled. But as we are opposed to compromises of a scientific nature, we shall dismiss the mixed system as one not liable to meet with much favour from engineers. double system is indubitably that to which we give the preference on all accounts. It is that adopted in the largest and most populous city in the whole world; it is the most rapid, most cleanly, most effective method of removing the offensive matter from human habitations, and most in consonance with civilized tastes and prejudices. That it is also the best in a sanitary point of view is evidenced by the circumstance that London, for its population in relation to area, is the most healthy city in Europe. The remaining argument against the double method, namely, that the sewage becomes so extremely diluted as to be of little or no value as manure, is abundantly disproved by the success of the Lodge Farm at Barking. Whatever objec-tions may be raised by the partizans of the single principle with respect to deficient ventilation is equally applicable to their own case. If sewers which convey sewage matter alone can be properly ventilated, there is no earthly reason why those conveying, in addition, other drainage cannot be also constructed so as to allow of the escape of gases and effluvia in the proper places. But the truth of the matter is, that if the drains are properly trapped and properly constructed upon a scientific as well as practical design, there is not the least fear of bad ventilation, silting up the bottom, or choking, or any other of the thousand and one difficulties that the enemies of the system are pleased to invent.

## THE HEATON STEEL PROCESS.

IT is exceedingly interesting to note the anxiety with which the process for the improvement in the manufacture of steel John Heaton, of the Langley Mill, in the Erewash Valley, is regarded not only by the vast iron industry of this country, but also by that of the Continent. In the commencement of the present year, a French commission of inquiry, headed, with the sanction of the French Government, by M. Gruner, Inspector-General of Mines in France, and Professor of Metallurgy in the Imperial School of Mines, spent four days at Langley Mill, and after having witnessed the conversion of their own impure pig iron into excellent steel, and verified the cost of production, decided in favour of the adoption of the process. This event is unquestionably one of the most important and honourable testimonials which have yet been adduced to the efficiency of Mr. Heaton's system of conversion. The vast industrial and commercial interests involved necessarily invest the solution of this metallurgical problem with an importance which raises it above the personal differences of rival patentees, however eminent and entitled to respect; and the great question at issue has arrived at a stage when the British public look for practical action in this matter. In the MECHANICS' MAGAZINE of October 30 last year, we published a succinct account of the process, and engravings of the plant at Langley Mill. For the purpose of keeping our readers au courant of the present position and progress of this invention, we propose to furnish a condensed summary of the correspondence which has recently attracted so much attention, regard being had to the principal issues raised by Mr. Heaton and Mr. Bessemer respectively, in the two letters of these gentlemen, published in the "Times," that of Mr. Bessemer, of the date of December 19, and that of Mr. Heaton, in reply, dated December 31. The text of the reet drainle the rebelonging to the double plan. It is, in fact,
annels, and
That irrimight be regarded in the light of a kind of

we shall best serve the interests of the public by presenting the substantial points of these letters in a condensed form. Besides, several collateral issues have been raised in the course of this correspondence which have but a very partial bearing upon the great question at issue, so that it is desirable to disencumber the subject of much that has been advanced.

Mr. Bessemer, in his letter which appeared in the "Times" on the 19th of December last, distinctly denies that Mr. Heaton can make steel as good as his, and at a less cost, from the same materials, with a plant costing vastly less, because Mr. Heaton employs 28s. worth of nitrate per ton, in lieu of using atmospheric air; nor does this extra expenditure produce "cast steel," and, therefore, the further cost incidental to a second melting must be added. He further states that 10 per cent. on the cost of the Bessemer apparatus does not amount to more than 2s. per ton on the steel made by it, which shows a loss on the nitrate process. Mr. Bessemer frankly admits that he cannot make good steel from inferior brands rich in sulphur and phosphorus, as Cleveland and Northamptonshire pig; but he says the iron he is buying of the highest quality, at 65s. to 70s. per ton, costs less for the ton of steel produced than the low class of pig irons named, when the 28s. worth of nitrate is added, making the materials of a ton of Heaton crude steel cost more than the materials used in the Bessemer process, whilst the latter yields cast steel, to obtain which Mr. Heaton must re-melt at much cost. Mr. Bessemer also denies that Mr. Heaton can make good steel and from as cheap from the commonest pig as he—Bessemer—can from the most expensive brands, which is but a corollary of the previous proposition, if demonstrated. Mr. Bessemer states that the loss by his process is 121 per cent.; whereas by the Heaton process the waste or loss cannot possibly be less.

In reference to the validity of Mr. Heaton's patents, Mr. Bessemer avers that the use of nitrate is not new or exclusive, and, further, that inasmuch as the effect produced by it is due to the streams of oxygen generated by its decomposition, and which are analogous to the streams of oxygen contained in his blast, Mr. Heaton's process would be such an infringement of his, if he produced fluid cast steel, that he might have opposed Mr. Heaton's disclaimer, and that Mr. Heaton owes the present validity of his patents to this magnanimity. Mr. Bessemer mainthis magnanimity. Mr. Bessemer maintains that one of the conditions of his own claim is the retention of the malleable iron or steel in a fluid state, and the pouring of it while still fluid into ingot moulds; and that upon this point of fluidity hangs the whole question of infringement by Mr. Heaton

of his (Mr. Bessemer's) patent.

Such are the leading points of Mr. Bessemer's letter of the 19th of December. On the 5th of the present month, the "Times" published certain extracts from Mr. Heaton's letter of December 31, in reply to the foregoing, as containing the "material parts." A remonstrance from the solicitor of the patentee, however, appeared in the "Times" of the

that the first product of his process is crude steel, but he denies that Mr. Bessemer has any right to question his capability of turning out, by means of a furnace, ingots suitable for making rails, because such was not certified thereto by Dr. Miller, who reported on the process. All that Dr. Miller was invited to testify was the capability of the process to make of certain attested pig—1st, true steel; 2nd, crucible tool steel; and, 3rd, wrought iron. Mr. Heaton proceeds with the following, which was published in the "Times":-

Mr. Bessemer flatly contradicts my statement that I can make steel as good as his own, and at a less cost, from the same materials. I am contented to appeal to facts, and these will shortly come before the world, verified by a competent and disinterested authority. An impartial French commission, headed, with the sanction of the French Government, by M. Gruner, Inspector-General of Mines in France, and Professor of Metallurgy in the Imperial School of Mines, have, as I led you to expect, just spent four days at Langley Mill, and after having witnessed the conversion of their own impure pigiron into excellent steel, and verified the cost of production, have taken away with them evidence which must carry conviction to all who are interested in establishing the truth. Now, I do not feel called Mr. Bessemer flatly contradicts my statement that must carry conviction to an who are interested in establishing the truth. Now, I do not feel called upon publicly to divulge my cost sheet—open however, as it is to inspection for legitimate purposes—simply because Mr. Bessemer chooses to insinuate, without warrant, that I cannot turn out "steel rails" by my process at less cost than "Bessemer rails," in the face of my assertion that I am turning out steel rails without remelting the product of my converter, at a cost with which no Bessemer steel can compete.

Mr. Heaton continues, and draws attention to the statement of Mr. Bessemer, that his first-class pig does not cost more than from 65s. to 70s. per ton, and yet the market price of his rails are £12 per ton. There must, consequently, be a large margin of profit left. But he denies that such pig can be bought for 70s. a-ton. The highest class Workington pig was at 80s., on December 19. But, assuming that Mr. Bessemer's quotation were the current price, the cost of the cheap atmospheric air, which is, at the very least, 5s. plus the extra cost of the requisite after dose of swiendleign (no loss than 8s.) being Mr. of spiegelcisen (no less than 8s.), brings Mr. Bessemer's raw material to 83s., or 93s. per ton if the current quotation be taken, while the cost of low-class pig, say 42s. plus 24s. for the nitrate, brings the Heaton raw material to but 66s. As to the waste by the Bessemer process -which Mr. Bessemer affirmed, in his letter, was only 121 per cent.—Mr. Heaton states, on the evidence of several of Mr. Bessemer's licensees, that 171 per cent. is the

minimum waste to which they have attained.
Mr. Heaton alleges that Mr. Bessemer exaggerates the cost of the nitrate and the quantity employed. "With less than 1½cwt. perton," writes Mr. Heaton, "I have produced per ton," writes Mr. Heaton, "I have produced excellent steel this week, in the presence, and to the entire satisfaction of M. Gruner, Baron G. d'Adelsward, and M. Thieblemont, the able representative of M. de Wendel, from white forge pig, produced at Baron d'Adelsward's works, at Longwy, in the department of the Moselle, from collitio ore, similar in composition to that of Northampers and the state of th similar in composition to that of Northamp-

what is taking place at his own. I will not then what is taking place at his own. I will not, therefore, accuse him of wilful concealment of facts, but, in corroboration of my former statement, I am prepared to bring forward evidence, upon oath, that a twelve-hole crucible furnace has been in use for seven years and upwards in Mr. Bessemer's own works, in Carlisle-steet East, at Sheffield, and that it has been there the common practice to run the steel out of his converter into a large cistern of water, from which the granulated metal is collected, and re-melted in-crucibles for the production of tool steel.

Mr. Heaton next proceeds to complain that Mr. Bessemer, professing to pronounce ex cathedra a condemnation of the Heaton process, has never taken the slightest notice of the tests of the metal manufactured, as certified by Mr. Kirkaldy, who has reported that steel made from pure Clay Lane No. 4 forge pig, bore 53 tons to the square inch, and that Butterley bore 45 tons, while the wrought irons from these brands bore 25 and 24 tons respectively. Since the date of these reports, Mr. Kirkaldy tested the steel made under the eyes of the French Commission, from the impure oolitic French pig, up to a breaking strain of 55 tons to the square inch. Mr. Heaton then proceeds to enter into a purely personal question, which, nevertheless, may be readily excused, since Mr. Bessemer had opened the matter. Mr. Heaton says:—

Feeling it to be necessary to account to the public for his taking out three patents for the use of nitrates, Mr. Bessemer professes to state his real motive for so doing. The motive suggested by the latter half of his letter is that he had been desirous only of or instetter is that he had been desirous only of protecting himself against infringements by me of his atmospheric patents, and he leads the reader to infer that this desire arose after the abortive issue of certain negociations with him, initiated by ma. I ask, in simple justice, to be allowed to refute both statement and inference. To prevent the public being misled, it will suffice to state the fact that Mr. being misled, it will suffice to state the fact that Mr. Bessemer's first patent for nitrate was taken out in December, 1867, whereas I never saw Mr. Bessemer till March, 1868. Mr. Bessemer's statement is, that early this year (1868), one of the proprietors of Heaton's patents endeavoured to persuade him to take an interest in them on favourable terms, and that he declined to do so. I most unequivocally contradict this statement. At the beginning of this year my patents were exclusively in my own handa, and I had no idea of disposing of them either to my present partners or to any other person, though I had been frequently solicited to do so. My visit to Mr. Bessemer in London, on March 3, was paid from no wish of mine to negociate with him, but in con-Mr. Bessemer in London, on March 3, was paid from no wish of mino to negociate with him, but in consequence of an intimation conveyed to me that he wished to see me; and neither on that nor on any other occasion did I, nor any person authorized by me, or by my sole partner at that time, or by my partners since, "endeavour to persuade Mr. Bessemer to become interested in my patents upon favourable conditions," or upon any conditions whatsoever.

The "Times" supplies the next paragraph, which brings us to the end of the letter. "After such evidence as this," writes Mr. Heaton,

It matters nothing what the product of my process is called by Mr. Bessemer, and I do not need Mr. Bessemer's unsolicited approval of what he has never seen, while I am able to produce, as I have already told him, a perfectly homogeneous steel, and cheaper than he can make, even if he could make it from such brands as I employ. I am not aware that it is necessary, in all steel making, for all time to come, that it should resemble Bessemer's in its successive stages generally when the all time to results are supprised. as containing the "material parts." A remonstrance from the solicitor of the patentee, however, appeared in the "Times" of the following day, pressing the consideration that, as the entire letter of Mr. Bessemer, containing some singular statements, was published, it was incumbent upon the same journal to publish a full reply. There can be no question that it was a grave mistake to insert Mr. Bessemer's diffuse letter, and we have before us a copy of Mr. Heaton's reply in extense, and we would willingly limit ourselves to the extracts published in the "Times," but the charges made by Mr. Bessemer, which will be fully understood by the reply, are serious, and we shall proceed to supplement the published extracts by an accompanying summary of the portions of the letter which were comitted. Mr. Heaton's letter is menting gives tool steel, and tool steel is to which were omitted. Mr. Heaton's letter is menting gives tool steel, and tool steel is to which were omitted. Mr. Heaton's letter is milling gives tool steel, and tool steel is to which were omitted. Mr. Heaton's letter is milling gives tool steel, and tool steel is to which were omitted. Mr. Heaton's letter is milling gives tool steel, and tool steel is to which were omitted. Mr. Heaton's letter is milling gives tool steel, and tool steel is to which were omitted. Conceding, for the sake of nitrate of soda were common property, or, use of nitrate of soda were common property, or, use of nitrate of soda were common property, or, use of nitrate of soda were common property, or, use of nitrate of soda were common property, or, use of nitrate of soda were common property, or, use of nitrate as successary for the secretained patent. It was evidently supplied to which is necessary for the useful application of the nitrate process is of the essence of application of the nitrate process is of the essence of application of the nitrate process is of the essence of application of the nitrate process of the essence of application of the nitrate process is of the essence of application of the nitrate process is of the essence of application of the nitrate process is of the essence of application of the nitrate process is of the essence of application of the nitrate process might to Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer has appreciated its to show how much Mr. Bessemer declares elements of my invention. Mr. B I claim what I affirm and have found to be the

Mr. Bessemer, well knowing that the fact of my success, which he still affects to dispute, has not, as he says, been before the public for twelve months, but says, been before the public for twelve months, but says, been before the public for twelve months, but says, been publicly notified in your city article of October 26, been publicly notified in your city article of October 26, been publicly notified in your city article of October 26, it is masters "have not rushed in a body to take iron masters "have not rushed in a body to take iron masters before its success was known. He conlicences "before its success was known. Important him to induce them to adopt his own. Important him to

disapproves.

Mr. Bessemer, having gratuitously provoked a discussion intended to damage my patent, retires from the controversy. In felicitating him upon the cossation of his duties as public monitor, I will but cossation of his duties as public monitor, I will but sak him what would have been his opinion of a fellow labourer in the same field, who, during the five low labourer in the same field, who, during the five low labourer in the same field, who, during the five ondeavouring in vain to convince the iron world of endeavouring in vain to convince the iron world of the value of his invention, had taken similar steps to prejudice him which he has adopted towards me to prejudice him which he has adopted towards me. He admits his inability to deal with my materials. I assert my perfect competency to do so, and thereby to "add at least ten millions a-year to the wealth of the country." the country.

The annual circulars of the iron trade which were issued at the beginning of the which attaches to this process. Messrs. Bird, Messrs. Rogers, Messrs. Shaw and Thompson, Mesers. Griffiths, and other well-known firms, are unanimous in expressing their belief that before long rails of a highly durable character, perore long rails of a nignly durable character, equal to Bessemer rails, will be produced at a more moderate price. Judging from the eminently satisfactory results which have attended the working of the Heaton process, attended the working of the Heaton process, and looking at its bearing upon the manufacture of iron and steel, we have no hesitation in pronouncing it to be one of the most valuable and important inventions of the day, and one for which it is not difficult to predict highly successful future.

TELEGRAPHIC PROSPECTS.

THE present year commences far more favourably for telegraphy than did the last, and, indeed, it may with safety be said that there is more hope of telegraphic extension now than there has been for some years. Our last numbers have presented to our readers a retrospect of telegraphic progress during the retrospect of telegraphic progress during the past year; it will be now our object to throw some light upon the works which will be completed during the present year, and upon those that will most probably be undertaken.

By the middle of the year, the transfer of our network of internal telegraphy will have taken place: the enormous amount of wires

taken place; the enormous amount of wires, instruments, and matériel belonging to the various telegraph companies, will have passed from their hands to the Postmaster-General, for the carrying out from that time the telegraphic services of the country by the ad-ministration of the Post Office. Many view the change with gloomy ideas of the State control, but we cannot share those ideas, but, on the contrary, look forward to an improved telegraphic service as the result of the change telegraphic service as the result of the change from a series of opposing companies to the uniting of the whole under one system. A general reduction of tariff, from a necessarily decreased amount of expenditure, may be regarded as an early consequence of the transfer, bringing about a large increase of transfer, bringing about a large increase of business, for telegraphy will then be accessible to many to whom hitherto it could only be used as a luxury, or in cases of imminent need.
That the service itself will not decrease in efficiency may safely be stated, for with the change the same efficient staff will be transferred. ferred. Extensions will be made to places hitherto unsupplied with telegraph wires. and we may congratulate telegraphists generally upon there being a greater prospect of work than there has been for some time.

At about the same date as the transfer of our telegraphic system will take place, the "Great Eastern" will have completed her freight of submarine cable, and will be starting from our shores to submerge the new cable from France to the United States. The works connected with this cable are progressing in the most satisfactory nanner; nearly 1,000 miles of the deep sea cable have been completed, a portion of which has been coiled on board a special vessel for carrying to the "Great Eastern"; the coiling on board will immediately commence and be continued uninterruptedly; the shallow water cable has interruptedly; the shallow water cable has been commenced and satisfactory progress made. The cable itself is of the most superior construction, and the conductivity of the connect conductor and insulating properties of copper conductor and insulating properties of copper conductor and insulating properties of the gutta-percha leave nothing to be desired, beyond the hope that the expedition will be successful, so as to allow of their excellent qualities being fairly tested in extensive communication between Europe and America.

munication between Europe and America.

A cable has just left us for Australia, intended to unite two of our colonies, Australia to Tasmania; it is about 200 miles in length, and we may probably hear by the initial middle of the year of the completion of this extension—a wise and useful enterprise of the Tasmanian Government.

On the return of warm weather, the completion of the cable, uniting Denmark to Russia may be looked forward to; a portion—that from Denmark to Bornholm—has already that from Denmark to Bornholm—stoppage of been completed. The sudden stoppage of navigation in the Baltic through the ice navigation in the Baltic, through the ice setting in, has delayed until spring the completion of the remainder, from Bornholm to Liban, the cable for which was carried out in the same ship. We shall then possess an almost uninterrupted line of submarine cable from our shores to Russia. It is also anticipated that a submarine cable will be laid

raising of the end off Havana, and joining the cable to the shore by means of the extra

cable lately sent out.

Very shortly, the "Tweed" and "Calcutta" will leave with 500 miles of cable for the Persian Gulf. Interruptions have occurred in this line chiefly at the same spots; alternain this line chieff at the same spous, and the tive land lines have been erected, where possible, to reduce the chance of total interpretation. But to make the chance still less, this length of cable is being sent out so as to duplicate the communication where these

interruptions are the most frequent. Communication with India has been frequently written about, as being very imperfect; steps have been, as far as possible, taken rect; steps nave peen, as far as possible, taken to improve the communication, of which the sending out this long length of cable is a proof, but still further and independent steps are being taken to increase the efficiency of are being taken to increase the efficiency of our telegraphic correspondence. The works of the Indo-European Telegraph Company are being rapidly pushed forward, and sufficient progress has already been made to satisfy us of the contractors carrying out their agreement for erecting a two-wire overland telegraph from Nordeney in the North Sea

to Teheran.

The preceding are works in progress, and of which there is every prospect of completion during the year; but there are several schemes which it may be safe to report will see brought out in the course of the year. Amongst the foremost of these is another advance towards improving our communication with the East, namely, an extension of the system completed last year by the Anglothe system Telegraph Company, to India.

This will be by a submaring apple from Succession of the Success This will be by a submarine cable from Suez, down the Red Sea, to Aden, and from thence down the Red Sea, to Aden, and from dience to Bombay. Confidence in submarine cables—especially deep sea—is now very great, and as the contemplated route is one of deep and as the contemplated route is one. water, there being every prospect of success, the bringing out of such a scheme to improve tne bringing out of such a scheme to improve our East Indian correspondence will be cer-tain to be taken up with confidence. The completion of such a line would give us then an almost uninterrupted line to India. The extension of telegraphy from Cuba to Jamaica, and from thence to Panama, is a project, it is hoped, which will be brought forward during hoped, which will be brought forward during the year, and other equally good and feasible schemes we hope will be placed before the public, creating such an amount of work that public, creating such an amount of work that we should be glad to see all our submarine cable factories fully employed. Our extentension on land will doubtless progress in the ratio of the increased demand for telegraphic correspondence and it is with great home of correspondence, and it is with great hope of good and useful extension, carried out with unvarying success, that we strive to penetrate

into the future of telegraphy.

As we have, during the past year, kept our readers early and accurately informed of telegraphic and electrical progress, making this subject a special feature of our journal, so, during the present year, encouraged by the success our endeavours have met with, we shall continue to supply our readers with the earliest information upon a branch of engineering which is daily increasing in interest and importance.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL AP-PLICATIONS.

EW MODE OF REFINING AND TOUGHENING GOLD INSTRUMENTS FOR REGISTERING AND MEASURING THE TIME OCCUPIED IN THE PERCEPTION AND ACKNOWLEDGMENT OF IMPRESSIONS ON THE SENSES.

NEW mode of refining and toughening gold has been introduced by Mr. F. B. Miller, of the Sydney Mint. Australian gold often contains The submarine cable from Key West, Florida, to Havana, the only unsuccessful work of last year, will, it is to be hoped, in a work of last year, will, it is to be hoped, in a very few weeks, become a success, by the a small amount of antimony, which renders it

mode of refining it was found did not remove the cause of the brittleness; and the refiners were somewhat puzzled, until the late Mr. R. Warrington discovered that in melting the gold with oxide of copper, the copper was reduced, and the antimony was removed in the form of oxide. In this way, however, the gold is alloyed with copper, which requires to be removed by another operation. Corrosive sublimate has also been employed to remove antimony from gold. In this process, the antimony is converted into a volatile chloride, and driven off along with the subchloride of mercury formed. This process, however, is an expensive one from the loss of mercury. As an improvement on both these modes of refining gold alloyed with silver and baser metals, Mr. Miller has adopted the use of chorine gas alone in the following way:—He first faturates a clay pot with a solution of borax, to prevent any absorption and loss of chloride of silver. Having placed the gold in the pot, it is covered with a closely fitting but unluted lid, having a hole bored in it. Through this, when the gold is melted, he passes a clay pipe down to the bottom of the pot. The clay pipe is in connection with a chlorine generator, and, by a suitable arrangement, a stream of the gas is driven through the metal; after continuing this for an hour or so, the crucible is allowed to cool, for the gold to set, and the chlorides which still remain liquid are poured A small amount of gold is removed with the chlorides, but this is easily recovered. The plan of reducing the chlorides of silver, adopted by the The plan author, was to set the slab of chloride between two plates of wrought iron, and immerse the whole in dilute sulphuric acid, leaving it there for about twenty-four hours, in which time the reduction was usually complete. The reduced silver is then dissolved in nitric acid, when any gold present is left undissolved. The loss of gold in these operations is said to be smaller than in the ordinary process of refining; the refinage is also completed in a shorter time, and is likely, we should think, to be as cheap as the old plan. Remembering, too, be as cheap as the old plan. Remembering, too, the complaints continually made of the nuisance of refining houses to neighbours from the acid vapours off, we may add that Mr. Miller's process can be made quite free frem objection on that score, by intercepting the excess of chlorine in a small chamber, furnished with a trickling stream of milk of lime.

"Quick as thought" has hitherto been used as a figurative expression, to denote an almost in-conceivably short duration of time. Few of those who make use of the expression would think it likely that the minute fraction of a second occupied in the perception of an impression by the senses, and the acknowledgment of it by the will, could be shown as accurately as our chronometers are made to follow the motion of the sun. But this it really accomplished by an instrument contrived by Professor Donders, the eminent oculist and physicist, of Utrecht. He has contrived two instruments, in fact, one of which he calls the Noëmatachrôgraph, or thought-time writer; and the other the Noëmatachromètre, or thought-time measurer. former, as we have said above, only registers the time occupied by the perception of an impression and the acknowledgment of it. A drum driven by clockwork is covered with lamp-blacked paper, upon which a point fixed to one branch of a pitchfork writes a series of waves, corresponding, of course, to the number of vibrations per second of time given by the note of the fork. In this way, it is easy to measure time to the 5-100th of second. By poculiar contrivances, anything which affects the senses, such as a prick to the finger, a spark to be observed by the eye, or a sound to be perceived by the ear, is at the instant made to register itself on the blackened paper. The observer, at the moment he perceives it, by a slight pressure of the finger also makes a mark on the paper, and the number of undulations between the two marks show the time occupied in the operations mentioned above. These operations, in fact, include three separate and distinct acts—the transmission of the impression to the brain, the action of the brain on the will, and the action of the will on the muscles. The same instrument registers as well the time occupied in an act of reasoning. The spark seen may be of different colours. If red it is to be acknowledged by the right hand, if green by the left. Denders finds that to make the distinction and acknowledge it, requires a much longer time than is required for the more simple operation before described. Some error, however, we think, is involved, for it is cer-

tain that one arm obeys the will much more quickly than the other, according as they are exercised. The thought-time measurer is a different sort of instrument. A falling weight strikes a drum and gives a sound, and produces a spark almost at the same instant of time, but with an interval accurately measurable. Thus, two sensations reach the brain almost at the same moment, and the problem to be resolved is which was produced first, the spark or the sound. instrument is so contrived that the anteriority of the sound or the spark can be varied at the will of the operator. The object of the instrument is to determine the space of time which must elapse between the emission of the spark or sound for the mind to be able to decide which was first, and thus arrive at the time required for a simple thoughtthe thought of anteriority. We often talk of slow men and quick men; for the future, we shall be able to measure exactly how quick or how slow they are in their perceptions and in their movements.

#### AN OPTICAL EXPERIMENT.

MR JOHN C. DOUGLAS, Government Telegraph
Department Madree has Department, Madras, has communicated the following interesting paper to the "Philosophical Magazine":—The following experiment (or return) experiments) furnishes a new means of demon-strating experimentally several laws of vision, particularly such as relate to visual direction; and, suitably modified, may possibly be of some practical value. Prepare a rather thick looking-glass by sprinkling its surface with prepared chalk or other fine powder, shaking off the superfluous powder so that the glass be covered with a thin coating of powder, through which the reflected image of the face may be seen with telerable distinctness.

If the glass so prepared be held fin. to Sin. from the face of the observer, and so that he can see a reflection of his own features, on shutting one eye the powder will no longer appear equally distributed, but will appear arranged in lines radiating from a point of the glass in front of the reflected image of the pupil of the eye used in observing the phenomenon. If (the appearance described above being visible) the observer moves his head with relation to the glass, the centre from which the lines appear to radiate and the whole system of lines move. If, however, the observer move his eyeball in its orbit, the glass and his head being stationary, the centre and system of radiating lines do not appear affected. On regarding the prepared glass with both eyes, he will see two centres, from which radiate two systems of lines, one centre being opposite to the image of the pupil of each eye. The appearance is not so distinctly seen, however, with two eyes as with one; and if one eye be stronger than the other, namely, more effective for purposes of vision when both are open, the system of lines appertaining to the weaker eye is less distinct than that appertaining to the stronger. The superior distinctness of the appear-ance when one eye only is used is due to the fact that the eyes mutually interfere when used together, for it is not necessary to shut one eye, but merely to interpose a sheet of card or other opaque body between it and the mirror. I have never failed to distinguish the radiating appearance in my own case, nor in the many cases in which I have endeavoured to show it to unscientific persons; and I believe, if only one eve be used at first, and the instructions given above be strictly adhered to, the appearance may be readily seen by any person; but as I have heard of an instance in which the phenomenon could not be distinguished, I have thought it necessary to give rather minute instruc-

The phenomenon is so easy of explanation that it is not necessary I should explain it; I will therefore confine myself to pointing out that the lines seen represent the apparent directions of the lines ioining the particles of powder and their images, and it is evident that the centres of the systems of lines are in the perpendiculars to the surface jof the mirror drawn through the centres of visual direction. The apparatus may be modified in accordance with the wants of each observer, the principle upon which its construction is based remaining the same; the glass may be of any attainable thickness; a glass plate may be placed in front of the mirror at various distances from it to carry the powder; engraved lines, dots, &c., may be

employed in lieu of powder; figures or other characters may be written on the mirror or glass plate if required; and the whole instrument may be suitably mounted.

The applications of the instrument described appear numerous; a few are given below:-Experimental proof is afforded of the principal lav linear perspective—as the existence of vanishing points, that they are in a line drawn through the centre of visual direction parallel with the vanish-ing lines, that vision with one eye only can be considered in perspective, &c.; the coincidence of visual direction and the centre of the centre of motion of the eyeball is proved by the immobility of the radiating lines when the eyeball only is moved, and their movement when the head is moved with relation to the mirror; a means is afforded of finding a point on a looking-glass, perpendicular to the surface drawn through which would pass through the centre of visual direction; a principle is afforded on which an instrument may be constructed for measuring the distance between the centres of motion of the eves. The instrument I used for this purpose consisted of a card divided along one edge by lines drawn on both sides of it, and as nearly as possible coincident; this card being held in front of a mirror and viewed obliquely, so that the divisions on the card and on its image might be seen at the same time (the card being held with the divided edge horizontal), two lines on the card were seen to coincide with the images of two lines corresponding to them on the other side of the card; and the distance between the two lines so coinciding with reflected lines being read off on the card, gave the distance between the centres of motion of the eyeballs. This instrument admits of great improvement, and it will be evident that its delicacy may be increased by increasing the proportion the distance between the image and object bears to the distance of the mirror from the eyes. It has been stated that, if no apparent motion could be produced in a distant object by closing one eye after having covered that object by another nearer the eye, the eye so closed must be inoperative when both eyes are used, the greater perfection of the one eye obscuring altogether the effect of the weaker organ. And so far as apparent direction is concerned. the experiment seems conclusive. But this view appears to need modification; for in a case in which both systems of lines were distinctly visible simultaneously, proving both eyes were employed, no apparent motion could be produced by closing the left eye; and although the left system of lines was fainter than the right, and the left eye was undoubtedly weaker than the right, the fact that the system appertaining to the left eve was distinctly visible when both eyes were used simultaneously, proves that in regarding the mirror both eyes were effective. It appears, therefore, that the powdered mirror affords a delicate means of detecting the share each eye has in vision, of exposing their inequalities of strength, and of detecting if both are actually effective when used together-in the last, being more delicate than the apparent-motion test.

Sir David Brewster (Optics, p. 294), has stated that the centre of visual direction coincides with the geometrical centre of the eyeball; but it has been objected to this, that Volkman's experiment visual direction proves that the lines of visual direction cross each other in a point anterior to the geometrical centre, and that calculation will show this is inconsistent with the curvatures and refractive powers of the humours composing the refractive media of the eye; but as, in the powdered-mirror experiment, the grain of the powder seen singly and forming the centre of system of lines marks the point through which a perpendicular to the surface of the mirror represents the line of visual direction, and as this line is immovable when the eyeball is moved, it follows that this line passes through a point the eyeball stationary with regard to the eyeball. wherever the centre of visual direction may be, it is the centre of motion, if not the centre of figure of the eyeball.

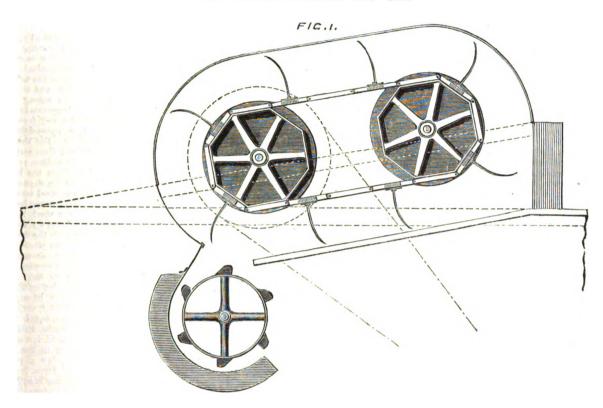

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending January 9, 1869, was—on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 17,204; Mevrick and other galleries, 3,244; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 2,416; Meyrick and other galleries, 305; total—23,162. Average of corresponding week in former years, 10,562. Total from opening of Museum—8,051,092.

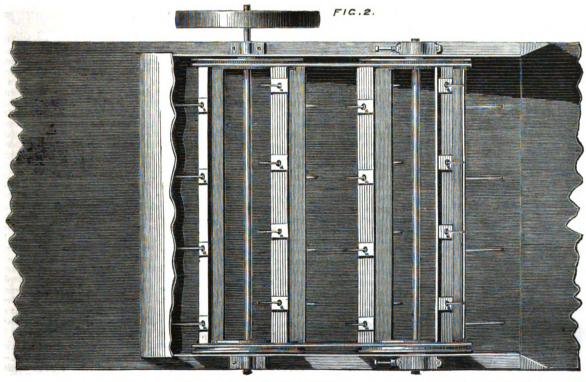

<sup>•</sup> The effect was most striking when the powder was very thinly and uniformly spread over a piece of plain glass placed before the mirror, at such a distance that the powder was rather less than half-an-inch from the reflect-ing surface.

## SELF-FEEDING THRASHING APPARATUS.

BY MESSRS. HAMBLING AND SON.

### HAMBLING'S SELF-FEEDING THRASHING APPARATUS.

THE accompanying engraving represents a self-feeding apparatus for thrashing machines designed and patented by Messrs. Hambling and Son, of East Dereham. Instead of feeding the crop to be thrashed by manual labour to the beating drum of the machine, as is usual, endless chains, driven from any convenient part of the machine, and fitted with teeth or spikes, are arranged to rake the corn forward along a platform to the mouth of the corn forward along a platform to the mouth of the machine. By this arrangement, the crop is

more evenly distributed; there is no loss of corn by escape from the mouth; one man less is required escape from the mouth; one man less is required in feeding the machine; and his labour is considerably reduced, as in a position of comparative ease, he is able with a fork to guide the corn to the feeding teeth, and all liability to choke the apparatus is prevented. If the teeth take the corn at a faster rate than the machine can thrash it, the superfluous quantity will be brought back over the

workpeople so frequently occurring from the exposed situation of the revolving drum in the ordinary thrashing machine. Fig. 1 in our engraving is a vertical section, and fig. 2 a plan of this improved action. These machines have already been he is able with a fork to guide the corn to the feeding teeth, and all liability to choke the apparatus is prevented. If the teeth take the corn at a faster rate than the machine can thrash it, the superfluous quantity will be brought back over the top and taken round a second time. The mechanical arrangement is so simple as not to be likely to get out of order, and the last, but not the least, advantage is the sure protection afforded against those fearful and often fatal injuries to proved action. These machines have already been awarded the first prize of a silver metal, in competition with many others, and the list of testimonials now before us as to their efficiency is such as to justify a belief that the employment of this apparatus will be general, especially as it can be readily applied to any existing construction of machine. We may add that Mr. T. C. Hambling, of 7, Westminster Chambers, Victoria-street, London, is the

#### ON LATENT HEAT. By J. C. DYER, Esq.

THE origin and nature of heat having engaged so large a share of scientific attention of late years, and directly conflicting principles in physics having been assumed, to explain calorific pheno-mena, render it desirable to obtain, if we can, some reliable tests of the several grounds on which the opposing theories are based. On the one side it is affirmed that "heat is a material element pervading the universe." On the other, "that it is, in ing the universe. On the other, "that it is, in fact, a nonentity, and merely the result, or consequent effect, of the exertion or expenditure of moving forces." In purely physical inquiries we must be guided by ascertained facts, rather than by authority, even of the most eminent physicists; wherefore I shall adduce some of the well-known facts bearing upon the points at issue. The materiality of heat cannot be sustained, except upon the admission of Dr. Black's doctrine of latent or specific heat in bodies; on this assumption, then I shall cite some of the cases that go to prove the existence of heat in bodies, beyond what is sensible or thermometric in them; and, therefore, in a neutral or latent state. And, first, I take the results of the carefully conducted experiments of Dr. Fairbairn, showing the relations of heat and water in their different forms of union. The following passage is from his valuable work:—"Useful Information for Engineers," pp. 3—4. "When water attains the temperature of 212deg. Fah. under the atmospheric pressure, it boils and gives off steam, which, when slowly formed, contains about 934-6deg. of latent heat, or heat not indicated by the thermometer; if to this be added the sensible heat of 212deg., we have 1,146-6deg. of heat required to raise, say 1lb. of water into steam, under the atmosphere of 14.7lb. pressure. But at a pressure of 25lb. per inch, the boiling point rises to 240deg., at 50lb. to 281deg., and at 100lb. it is of 3273deg. of temporature." The temperature or of 3274deg, of temporature." The temporature or sensible heat in steam is thus gradually raised by the increasing pressure or density of the steam, and saturated steam, or steam raised in a boiler over water, is found to take up nearly double the quantity of water to form steam of double density or pressure; but the latent heat in steam is directly as the quantity of water converted into steam, whilst the sensible heat in it is only as above stated, viz.:

stated, viz.:—
From 212° at 14·71b., to 240° at 251b., increase 28°

" 240° at 251b., to 281° at 5001b., " 41°

" 281° at 501b., to 827½° at 1001b., " 46½°

The decreasing latent heat in steam is found to be nearly as the increasing sensible heat, or, in other words, the absolute heat is nearly in proportion to the water changing its form of a liquid to an elastic

By the increase of sensible heat, all liquids and solids are gradually expanded, and by the abstrac-tion of such heat they are contracted in bulk; but the degrees of expansion and contraction are different in bodies, as shown in the mercurial and spirit thermometers, the Wedgwood pyrometers, and the different metallic rods used for compensation balances and pendulums. In all such cases, the gradual changes of bulk by the gain and loss of sensible heat, the law governing the changes is quite distinct from that which rules in the cases of sudden changes of water and other liquids into which changes of water and other liquids into steam and again back into the liquid form, and by which changes of constituent forms, absorbtion and liberation of heat takes place, to the extent before shown, beyond what is indicated by the thermometer.

It thus appears quite clear that the entering of heat latent in steam is a consequence of water being converted from its liquid state to that of aqueous vapour, and the reappearance of the same heat, in a sensible state, when the steam is converted into water, is equally the obvious consequence of the change. Such reciprocal changes of the constituent forms of bodies clearly serve to explain the changes of heat into its latent and sensible forms, as before stated. We find, too, all solids show the gradual loss and gain of heat, however high the temperature may be raised, unless the body itself be converted into a liquid or vapour, and then the sudden absorbtion of latent heat in them is found, as in the case of steam from water. Taking the total amount of sensible from water. Taking the total amount of sensible heat in steam of 50lb. pressure (as in common use) at 28ldeg., as above shown, and the latent heat in the same steam, as given in the tables, at 2,670deg., the total absolute heat in such steam will equal 2,951deg. Fah. Now, if the entire heat so contained in steam of 50lb. pressure

were to remain thermometric heat, it would, of wore to remain thermometric near, it would, of course, raise the temperature of the pipes and engine to the same degree, which would soften the metal and destroy the vessels conducting it, to say nothing of the danger of attending or even approaching the engine. I am aware of the allegaproacning the engine. I am aware of the allega-tion that heat, not appearing sensible in steam beyond the boiling point, is "because of the ex-pansion of water into some 1,640 times its liquid bulk when converted into steam." Well, even though we allow this way of accounting for the insensible state of the heat in steam, still the fact remains that the 934 6deg. of heat exists in the steam, for that amount is carried over by it to the condenser, and reappears as sensible heat in the water.

From these facts it would seem that the term "latent heat" is the only matter in question; for the entire amount of heat, say of 934deg., that disappears as sensible heat in the steam reappears sensibly in the condenser. It is quite familiar to all, that by the forming of steam, as in common evaporation, sensible heat is absorbed, and the air cooled, also that when aqueous vapour is condensed heat is given out; so that heat is thus continually changing its form from sensible to latent, and vice versa, by the changes of water into the alternate states of liquid and vapour. The same phenomena, but to a less extent, appears in the freezing and thawing of water, namely, when a pound of ice is melted in warm water, the amount of sensible heat required to convert it into water is about 140deg. Fah. more than appears in the water, viz., the heat to maintain its liquid form is 140deg. in excess of what is contained in the state of ice at the melting point; and when the same pound of water is again converted into ice it gives out the said 140deg, of latent heat from the liquid in the act of freezing. A hundred other cases equally familiar might be adduced to show the disappearance and reappearance of sensible heat in bodies upon their changes of constituent forms, as solid, liquids, and vapours, and in all such cases the increments and decrements of heat, in its sensible and latent states, take place suddenly, just as the bodies undergo those changes, and in strict ac-cordance with known scales of specific heat in them, as published in the tables of such heat.

I may here glance at another aspect of latent heat. We have seen that steam of double density, viz., from 25lb. to 50lb. per inch, is raised by the addition of 41deg. of sensible heat; and, again, from 50lb. to 100lb. pressure by the further absorbtion of 46\frac{1}{2}deg. of sensible heat. These small accessions of heat in its sensible state are accounted for by the survive of these than the sensible state are accounted for by the amount of latent heat in the extra water, as before stated; for, to double the pressure of isolated steam requires some 460deg, of sensible heat. If we look to the 140deg, of latent heat in water over that in ice, it will be seen that in lieu of being expended by the heat thus absorbed in melting the ice, the water is contract d in bulk; for at temperatures from 32deg. to 40deg. ice floats with about one-sixth of its bulk above the surface. The notion, therefore, that heat ceases to be sensible by reason of the expansion of bodies when it becomes latent in them is clearly shown to be a fallacy.

I come now to notice the latent heat that becomes sensible by the union of a solid with a gas.
The latent heat in oxygen and carbon being in excess of that in carbonic acid, by the formation of excess of that in carbonic acid, by the formation of this acid in breathing, the supply of sensible heat is duly maintained to keep up the temperature of warm-blooded animals, and the excess of heat evolved in the lungs is carried off by converting water into steam, which passes out with the breath. If the whole heat so evolved were to breath. If the whole heat so evolved were to remain sensible it would destroy the living func-tions. Many other mutations of heat depending on the vital energies were explained in a former

solids, liquids, vapours, and gases, is also propor tionate to their bulks, in the same form; wherefore, by compressing a body of any kind, sensible heat is given out, and by expanding it sensible heat is re-absorbed, or taken up in a latent state; so that mechanical forces continually acting among bodies around us bring about the alternate conditions of heat so familiar to everyone. therefore, is thus plainly seen why sensible heat in bodies is produced by mechanical forces. But this affords no ground for assuming the generation de novo of any heat by the exertion of any force—either chemical or mechanical.

We have sensible heat from the solar rays, and We have sensible near from the solar rays, and that produced by combustion, and other chemical changes of bodies, but have strong grounds for concluding that all forms of sensible heat produced by mechanical forces are derived from the latent heat, rendered sensible by compression or the abratical of bodies by graph forces. But the alternation of bodies by graph forces. sion of bodies by such forces. But the alternation of sensible and latent heat thus caused by mechanical action is seen in an endless range of com-But the alternation pressions and expansions from the lighting of a match in the air syringe to the showers of sparks issuing from the particles of steel torn off in dry grinding, and ignited by the intense heat from the compressed air between the steel blade and the grindstone. I need not enlarge on the numerous other facts in accordance with the foregoing, but may venture to say that those cited must be directly met by adducing others to show how sensible heat is made to come and go otherwise than by the changes of heat from one to the other of its states of sensible and latent, before the principle of such mutations of heat can be superseded by the new theory. To say that "work is done" when water passes into steam, equal to the heat entering the steam,—and, again, that when the steam is condensed mechanical force is excited equal to the heat reappearing in the water,—are naked assertions, with no shadow of proof to sustain them, for no mechanical force is called into action in forming the steam, nor is any such force exerted by it in returning the water. So that force exerted by it in returning the water. So that force has nothing to do with those changes, except it be the chemical forces, depending on the known relations of heat and water. We all know that there is nothing occult in the laws of dynamics, and that all moving forces can be distinctly mea-sured, and their amount and direction plainly proved, which forbids the admission of any mys-

tery in the science of mechanics.

Now, in the face of these established laws, we find the following announcement by the able expounders before cited of the new philosophy, viz.:

"When the motion of a body is arrested, the
motion of the mass is transferred to a motion of the molecules—or particles composing it—and this motion is heat." And, again, that "mathe-matical formulæ have been deduced from it, and thus a quantity has been found, termed the me-chanical equivalent of heat." That the motion of the mass is transferred to the molecules is an assumption devoid of any foundation in known facts, for we have no means of proving any kind of dynamical action by such intangible, unknown, and suppositious molecules, or ultimate particles of bodies. And to base mathematical formulæ on such visionary forces and motions can hardly comport with the dignity of the exact sciences, or tend to shed any light upon physical truths, which, after all, must be sustained by known facts, rather than by theories, old or new. As these two theories are based on opposite principles, they cannot both be true; and without referring here to any of the other cases (adduced in former papers) that appear to prove the untenable nature of the new theory, I conclude by submitting the above short outlines of the phenomena resting on, and explaining, the doctrine of latent heat.

on the vital energies were explained in a former paper, and may be here passed by, with the remark that this entire class of changes, as in the case of respiration, are effected by chemical forces called into action by vital organisms. The alternate changes of sensible and latent heat depending on the constituent forms of bodies, and upon the chemical forces so called into action, might be shown in a hundred other cases, but the above will suffice to mark the principle on which the mutations of heat depend.

Apart, then, from the chemical relations of heat with other bodies, I proceed to notice some of the cases in which the appearance and disappearance of sensible heat that do depend on the action of mechanical forces; these are of so wide a range that only a few of them can or need be given. It must be kept in view that the latent heat in bodies, besides depending on their constituent forms, as

\* Literary and Philosophical Society.

#### INSTITUTION OF CIVIL ENGINEERS.

A T a meeting of the Institution of Civil Engineers, held January 12, Mr. C. H. Gregory, President, in the chair, the paper read was on coal-getting machinery, as a substitute for the use of gunpowder, by Mr. C. J. Chubb.

It was remarked that the improvements now

needed in the art and practice of coal-mining might be thus specified,—first, to ensure greater safety to the men employed in working, and, secondly, to obtain the coal in better condition, and, by preventing as much as possible the loss arising from waste, to make more fully available all the remaining resources of the coal fields. It was contended that the use of gunpowder and the operation of blasting must be altogether abandoned; and the problem to be solved was, what force could be applied which should be equally effective, and at the same time break the coal in a more perfect manner. The author thought some more simple and practicable means of getting coal by mechanical power could be devised than the costly, but skilfully contrived, coal-cutting machines. His first idea was to apply wedges, acted upon by hydraulic force, but he was induced to abandon that system, owing to objections to the use of wedges, and to adopt instead an apparatus consisting of twelve plungers, set side by aide in a steel bar, which plungers, when acted upon by water from a hydraulic pump, would separate the bar in which they were set from another bar, formed in the shape of a cover upon the plungers. The pressing apparatus was 25in. long and it was attached to a hydraulic pump by a tube 2ft. in length, so that it might be inserted into the coal to a depth of about 3ft. 6in. The apparatus with the cover on, was 4 in. in diameter. When by the action of the pump, the plungers had reached their limit of 2½in., and further expansion was needed, the plungers were readily brought back to their first position, by opening an escape cock for the water, when a liner could be inserted between the plunger and the cover: and this process could of course be repeated. In practice, however, it was found that the first expansion to 2\frac{1}{4}in. was more than sufficient. It was stated that the collective area of the plungers was 24 square inches, and as the pump could exert a pressure of 12 tons on the square inch, a total pressure of 288 tons could be brought to bear on the coal.

This apparatus had been tried in the South Wales district, where the coal was of the most varied description. It was observed that by the present description. It was observed that by the present system of blasting, it occupied, on an average, two men ten hours to break down and fill into trams 4 to 5 tons of coal, of which 20 per cent. was "small," and the remainder much shattered. On the other hand, with this apparatus, two men could readily break down 20 tons in one hour, which could be filled, when loosened, at the rate of 10 tons per man per day, the whole of the coal so obtained consisting of large solid pieces. Again, by the present system, in order to break down 500 tons of coal a-day, from a "four-foot" seam, a "face" of 600 yards was required, whether as "pillar and stall," or as "long work"; whereas, with this apparatus, the same quantity could be worked from 300 yards of "face." In this way there would be considered to the provided of the working 300 yards of "face." In this way there would be less space requiring to be ventilated, the working operations could be concentrated, and facilities would be afforded for effecting economy in other

respects.

The discussion was then resumed on Mr. Bidder's paper in conjunction with Mr. Chubb's, and not being concluded it was then announced that it would be continued at the next meeting, when, time permitting, the following paper would be read: "On New Ferry and New Brighton Piers," by Mr. H. Hooper, Assoc. Inst. C.E.

At the monthly ballot, the following candidates At the monthly ballot, the following candidates were balloted for and duly elected:—As members, Messrs. W. Anderson and F. W. Kitson; as associates, Messrs. C. J. Clarke, E. N. Clifton, T. Dyke, R. M. Green, T. Hennell, A. H. Kessner, F. L. O'Callaghan, W. W. Phipson, L. W. Pritchard, W. Stevens, W. H. Treverton, and M. Vidler. It was also announced that the following candidates had been admitted students of the Institution since the date of the last announcement:—J. Addy, J. Bau-mann, J. Brunlees, A. G. Fowler, A. C. Robson, R. Sharland, G. Stevens, and J. J. Stiles.

THE works at Creusot are constantly presenting some new feature of interest. Recently a new theatre was opened there, capable of containing from 700 to 800 persons, with pit, two galleries, and orchestra stalls, painted in white picked out with gold, and illuminated by means of a transparent ceiling. M. Morisot, of Creusot, was the architect.

SHIPBUILDING ON THE CLYDE IN 1868.

NE last week briefly summarized the shipbuild-W ing of the Tyne for the past year; we now give the results of a year's shipbuilding on the Clyde. From statistics of this trade during 1868, which, together with comparative tables for the six previous years, have just been published, it larger appears that during the year there have been larger appears that during the year there have been launched from the various building-yards on the river between Glasgow and Greenock, 227 vessels, with a gross tonnage of 174,978 tons. Of these the proportion were steamers, there having been launched no fewer than 8 war steamers, of 5,384 tons, 18 paddle steamers, of 6,291 tons, 82 screw steamers, of 81,241 tons, 8 screw hopper barges, of 1,900 tons, and 2 steam dredgers, of 485 tons. Of the above, all were iron vessels but four, registered as composite. Of sailing vessels, there were launched 78 (iron), of 63,799 tons, 16 (composite), of 13,313 tons, 14 (wood), of 2,234 tons. There were also launched 6 yachts of 381 tons. Of the steamers, no fewer than 8 war ships—namely, the were also launched 6 yachts of 331 tons. Of the steamers, no fewer than 8 war ships—namely, the "De Tyger," "De Buffel," powerful turret ironclads, built by Napier and Sons for the Dutch Government; the "Hart," "Midge Pert," and "Growler," composite gunboats, of 464 tons, built for the British Government by four different firms; the "Kwang-Tung" and "Shung-Tung gunboats, of 221 tons, built for the Viceroy of Canton by Messrs. Denny of Dumbarton. Among the merchant steamers launched, were the "Ohio," Canton by Messrs. Denny of Dumbarton. Among the merchant steamers launched, were the "Ohio," "Rhein," "Main," and "Donau," of upwards of 3,000 tons each, constructed for the North German Lloyd's; the "Holsatia," and the "Neva," of similar tonnage, for the Hamburgh and American Company; the "City of Brooklyn," for the Inman line; the "Samaria," for the Cunard line; and other powerful vessels for the great ocean routes. Compared with the statistics of 1867, there is a falling off in those of 1868 of 14 vessels but an infalling off in those of 1868 of 14 vessels, but an increase of tonnage to the amount of 60,000 tons, the number of vessels launched in 1867 having been 241, and the tonnage 114,598. The tonnage launched in 1868 is greater than during any of the previous six years, save 1864, when the amount was greater by 10,000 tons. The orders on hand for 1869 are much heavier than they were at the same date last year, so far as the amount of tonnage is concerned. At the close of 1867 there were 130 vessels, of 115,124 tons. This year the number of vessels is 123, and 129,400 tons. Of this number, three are Seriew armour-clads, of 10,188 tons—namely, the "Audacious," "Invincible," and "Hotspur," building by Napier for the British Government; three are paddle steamers, of 1,914 tons; 57 are screw steamers, of 70,600 tons; 58 are sailing ships, of 46,558 tons; and the remainder small vessels. The above orders do not include those of several of the principal shipbuilders, who decline to give publicity to the extent of their contracts.

#### NEW YORK SOCIETY OF PRACTICAL ENGINEERING.\*

THIS society held a regular fortnightly meeting at Room 24, Cooper Institute Building, New York City, on Tuesday evening, Desember 8, 1868. James A. Whitney, the president, in the chair. The subject for regular discussion was "Modern Improvements in Mining Apparatus," and the paper thereon was read by Mr. Wm. B. Harrison. paper thereon was read by Mr. Wm. B. Harrison. The writer treated at length the progress that had been made in mining operations and accessories, from the calabash used by the primitive savage to wash the golden grains from the river sand, to the costly and powerful stamping mills and carefully constructed amalgamating apparatus of the present day. He also spoke at length of the application of the new, but now comparatively well-known, explosive materials, nitro-glycerine, dynamite, &c. with reference to their use in mining and tunneling; and also embraced in his review sketches of principal pumping devices employed in English and American mines.

An interesting debate on various phases of mining followed the paper. A. W. Hall, Esq., gave a description of methods of mining in the Rocky Mountain mining regions, in which some years ago he had been engaged. The great difficulty in that region had been found in separating the gold from the black sand with which it is intermingled, the sand being heavy—about four times heavier than water. The trouble was, however, readily overcome by the amalgamating process. As formerly carried on with mercury spread in the bottom of the separating machinery, this process required an

" "American Railway Times."

excessive quantity of mercury; but an improved excessive quantity of mercury; but an improved method, which consists in coating copper with mercury so that a very large surface of the latter is presented to the gold particles, this difficulty is completely obviated, the quantity of mercury requisite being comparatively small. Mr. Hall described, in the course of his remarks, an apparatus which he had himself devised some years since, which, although requiring more mercury than the one last above indicated, was found in practice to be very efficient in separating gold from the materials in which it occurs in a finely divided state. This amalgamator is simply an elbow, or receptacle, formed in a conducting syphon, through which the fine materials are carried in suspension in water. The particles of gold are, of course, brought into immediate contact with the mercury, and their amalgamation thus secured.

At the request of the president, a gentleman present explained the system of hydraulic mining so exclusively in use on the Pacific coast. The water from natural reservoirs and mountain streams, often at a great elevation, is conducted by flumes to the neighbourhood or district where it is needed for use. From the flumes it passes into great canvas or duck hose adjusted to convey the water to the precise locality to be mined. By means of a movable hose with a nozzle, the stream is directed against the embankment to be torn down or disintegrated, with a force proportioned to the head of water. The earth brought down by this means passes into the sluices, which are arranged to contain the mercury for amalgamating. As the particles of gold come in contact with the mercury, they unite therewith to form an amalgam, which is removed from the sluices at suitable in-

tervals of time.

Dr. J. V. C. Smith, Ex-Mayor of Boston, gave an interesting sketch of what he had seen while travelling in Asia Minor, and other Eastern countries, expressing the opinion that much mineral wealth might yet be discovered in those ancient but remote regions. He made mention of an unique turbine waterwheel which he saw in operation under the charge of an Arab in one of the gorges of the Anti-Lebanon Mountains, in Palestine. The Arabs stated that wheels of similar character had been used by their ancestors for many ages. Dr. Smith also briefly sketched a personal interview with the celebrated Baron Von Humboldt, in which Humsian Empire, with all its gigantic cost, was maintained in a very great degree by the gold derived from the mines in the Ural Mountains.

A member stated, in brief, that in the treatment of gold containing sulphurets, calcination of the ore is essential, and that in this the employment of superheated stoam is found to be the most advantageous.

Mention was also made in the course of the discussion, that in many silver ores the pulveriza-tion should be effected when the ore is in a dry condition. For this purpose stamp mills are much to be preferred to other forms of pulverizing machinery. One of the best apparatus for such purposes operates on this principle. The ore is crushed and powdered by stamps in a closed chamber; a fan-blast carries the fine particles into another chamber, where they are allowed to settle, the accumulated powder being afterward subjected

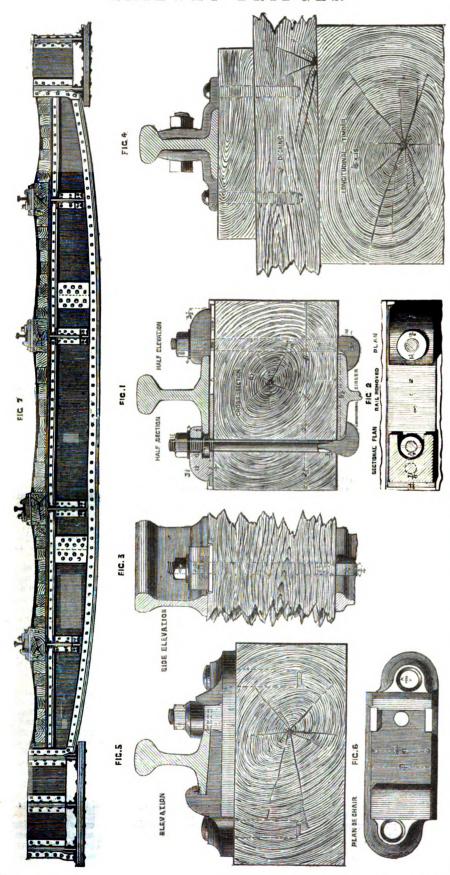

to suitable treatment to extract the silver.

The president remarked concerning the discovery of mines and deposits or the present metals, that their discovery had often resulted from mere accident, a statement which he illu-Carolina deposits, by two children who were playing in a mountain rivulet; of a mine in South America, in which a clambering hunter tore a shrub by the roots from a hillside, which disclosed the precious metal beneath; and of the great mines at Freiburg, in Germany, said to have been first found out by the upturning of the ore by a passing waggon wheel.

After a further discussion on topics relating to the mining of the precious metals, the meeting adjourned for two weeks. The subject at the next meeting will be "The Prevention of Disasters at

On Thursday week the Bywell Ploughing Society held its annual match at Stocksfield, near Newcastleheld its annual match at Stocksfield, near Newcastle-upon-Tyne, when upwards of thirty competitors were in the field. The first and second prizes in the All-England class were awarded to local men using Messrs. Ransomes ploughs. On Saturday last, at Heighington, Durham, not only the first and second All-England prizes, but also the first prize in the district class, were won by local men holding the same make of plough.

# PERMANENT WAY OF THE THAMES RAILWAY BRIDGES.

THE PERMANENT WAY OF THAMES RAILWAY BRIDGES.

W E have crossing the Thames within the metropolitan district, four railway bridges of large span, upon each of which a different system of permanent way has been adopted by the engineers of the several lines to which the bridges relate. It is our purpose to describe these various methods

of accomplishing the same object, and to lay their distinctive features before our readers. Commencing at the higher portion of the river, we will take the fine structure carrying the London, Chatham, and Dover, and the Brighton railways over the Thames at Chelsea, and which is known as the Victoria Railway Bridge. In the arrangement adopted here by Sir Charles Fox and Son, the engineers of the works, the permanent way is carried on longitudinal rolled iron bearers 9in. in

depth, 5½in. in breadth across the top and bottom flanges which are §in. thick, and weighing 35lb. per foot run. The details of the way appear in our engraving at figs. 1, 2, and 3, which show respectively a cross section, a sectional plan, and plan with rail removed, and a side elevation of the arrangement. A longitudinal timber rail bearer, 12in. by 8in., is placed upon the rolled iron girder, and upon this again the rail takes a direct bearing except where the fastenings are interposed. The rail, which is of the flat bottomed or contractor's section, is of steel and weighs 72lb. to the yard. The fastenings occur at intervals of about 3ft., and to receive them the longitudinal timber is cut away to a depth of five-sixteenths of an inch. In this is fitted a wrought-iron distance plate 11½in. long, 3in. wide, and ½in. thick; a slight clearance is left between the plate and the under side of the rail. The object of the distance plate is to make both of the bolts assist in keeping the correct gauge. The rail is held on each side by a cast-iron clip, which also takes into the distance plate. The whole of the parts are held together by two §in. hook bolts, which are inserted from beneath, and clip the top flange of the iron longitudinal bearer. The distance plate is first held down by a bastard nut, 1½in. diameter, the clip is then placed on, and in its turn is held by a 1½in. nut, which completes the system.

The system of permanent way adopted by Mr. Hawkshaw on the Charing Cross railway bridge is shown at fig. 4. The rail is of iron, and of the same pattern as that used on the Victoria Bridge. It weighs 75lb. per yard run, is 5in. deep, and about 4½in. wide in the foot. The roadway is formed with a curved surface, and the rails are therefore placed on longitudinal timber sleepers of varying thickness in order to bring the way up to a true level over all the rail surfaces. The rails are fixed to the longitudinal timbers by wroughtien angle chairs or brackets, placed in pairs at intervals of 2ft. 6in. The brackets are 6in. wide and about ½in. thick in section, and the rails are secured in them by ½in. screwed bolts, passing through holes in the web of the rail. At the joints, fish-plates and lin. bolts are used. The brackets are fixed to the longitudinal sleepers by ¾in. spikes. The longitudinal timbers are spiked down to the decking of the bridge, which is of 4in. timber, and is carried by longitudinal timber bearers 15in. by 15in. On the road bridges of this line, some of which are of very large span, a similar system of permanent way is adopted. The gauge of the line, however, is preserved by transoms of timber 6in. by 6in., which, in the 4ft. 8½in. way, are placed at intervals of about 6ft. In the 6ft. way the transoms are placed at intervals of from 12ft. to 20ft. These transoms are connected to the longitudinal timber by means of 1in. bolts passing through the latter, and of sufficient length to hold them well together.

The Cannon-street bridge, although not the next in succession, may be noticed here, as it belongs to the same company as the last—the South-Eastern. The permanent way on this bridge presents no special features, being simply the ordinary way of the line. This arises from the circumstance that the bridge is laid out for station purposes, and has numerous points and crossings which could not have been so conveniently worked out with the bridge of the ordinary permanent way of the line, which consists of a double-headed rail, fished, and weighing 75lb. per yard, laid at a cant of 1 in 20, the fish-plates are 1ft. 3in. long and 1in. thick, bolted with four 1in. bolts. The chairs are of castiron, and weigh from 28lb. to 30lb. each, the width at seat of rail being 5in., and the base of the chair being 13in. long by 5\frac{1}{2}in. wide. Each chair is sastened to the sleeper with two spikes. To hold the rail in the chair, oak wedges, 8in. long, are used. The sleepers measure 9ft. by 10in. by 5in., and are placed about 2ft. 6in. centre to centre throughout. The sleepers are buried on a few inches thickness of ashes, and thus the permanent way of the bridge is completed.

On the bridge at Blackfriars, carrying the Metropolitan Extension of the London, Chatham, and Dover Railway over the Thames, a different system again has been introduced. Messrs. Joseph Cubitt and F. T. Turner, the engineers of the line, have adopted the arrangement shown in figs. 5 and 6, which represent an elevation of the chair and sleeper and a plan of the chair. The timber longitudinal sleepers measure 14in. by 7in., and are laid directly upon the wrought-iron longitudinal bearers and the cross girders. The chairs are of cast iron and are placed 2ft. 6in. apart. The rails are of steel, and of the flat bottomed pattern, but

slightly smaller in section than those on the Victoria and Charing Cross bridges. The rail is kept in the chair by a lip on the outer side, whilst on the inner it is held down by a wrought-iron on the line rice. Seed when by a put and holt. The on the inner it is held down by a wrought-iron gripping piece, acted upon by a nut and bolt. The head of the bolt, which is tapered similarly to that of a trenail, is flush with the under side of the chair, through which it passes upwards, and thence through the wrought-iron piece to receive the nut. The chair is fastened down to the longitudinal sleeper by two compressed cak trenails 6in. long and 1 3-16in. in diameter. The cant given to the rail is 1 in 20.

The details of the bearers of the permanent way The details of the bearers of the permanent way and the flooring of the Blackfriars railway bridge, are shown at fig. 7, which represents a transverse section of half the bridge, between the outer and the inner main girders, the entire bridge being laid with four lines of way. The engraving shows one of the cross girders, which are placed 4ft. 4in. apart, attached at each end to the main girders its depth at the centre being 1ft. 9in. Immediately beneath the longitudinal timbers are seen the longitudinal wrought-iron rail bearers. The two in beneath the longitudinal timbers are seen the longitudinal wrought-iron rail bearers. The two in the centre are each 1ft. 6in. in depth, whilst each of the two outer bearers are but 1ft. 3in. in depth. The flooring consists of balks of timber laid longitudinally with the bridge, and stapping down him tudinally with the bridge, and stapping down in. each from the side to the centre of each way. The stepped or curved surface produced by this arrangestepped or curved surface produced by this arrange-ment is filled in with asphalte, which forms the top surface of the road. The foregoing oxamples of bridge permanent way show how opinions may vary as to the best method of accomplishing one and the same object, and although in some the end is attained by slightly better means than in others, there is yet great merit in all.

# THE NEW ELEVEN-INCH GUNS FOR

THE NEW ELEVEN-INCH GUNS FOR RUSSIA.

A BOUT five years ago, when the Russian artillery for made use of muzzle-loading rifled cannon, the Russian Government had ordered of M. Krupp a time cast-steel gun on that system rifled 11-inch bore, English measure. Since then, numerous experiments having been considered to prove the superiority of breech-loading guns throwing projectiles larger than the bore, the Russian artillery projectiles larger than the bore, the Russian artillery has decided on adopting these guns exclusively. At the time of this decision the 11-inch was in a forward state of manufacture as a muzzle-loader, the state of the state of the gun would be too thin for the slot for the breech-piece; but further experiments on the resistance of breeches of different thicknesses having demonstrated the possibility, the alteration to a breech-loader on Krupp's principle was made. This gun has been subjected to a prolonged trial of 400 rounds, the number fixed by the Russian authorities. The subjected to a prolonged trial of 400 rounds, the follow. 3gr. 3lb. The weight of gun, 25 tons, 11cwt. 3gr. 3lb. The weight of the projectile was prismatic powder. The initial velocity ecommunicated by this charge to this projectile was the subject of the gun stood the 400 rounds with this charge, and remained in a serviceable condition. The above quantities, as well as those which thaving been reduced from the Prussian denominations.

The breech-piece was Krupp's single-round wedge.

follow, are all in English measure, the equivalents having been reduced from the Prussian denominations.

The breech-piece was Krupp's single-round wedge. Two were furnished for the experiments, one was only used for that purpose; the other an ordinary breech-piece, in this experimental by one of the gas in the chamber, and which will be presented by one and all escape of gas was perfectly prevented by one of the charge of the whole broadwell ring. The explosion of the axis of the bore of rounds. The explosion of the axis of the brace-h-piece. The gun was sponged out after the projectiles there was the slightest appearance of leading in the groeves. The gun was sponged with soapy water, which suffices for the whole briefs the lead coatings of the projectiles there was the slightest appearance of leading in the groeves. The slightest fouling. The fectively removed the slightest fouling. The firing by the passage of the gas did not exceed the slightest fouling. The firing by the passage of the gas did not exceed the slightest fouling. The firing by the passage of the gas did not exceed the slightest fouling. The firing by the passage of the gas did not exceed the slightest fouling the firing by the passage of the gas did not exceed the slightest fouling the firing by the passage of the gas did not exceed the slightest fouling the firing by the passage of the gas did not exceed the slightest fouling the firing by the passage of the gas did not exceed the slightest fouling the firing by the passage of the gas did not exceed the slightest fouling the firing by the passage of

for a breech-loader, and the new breech-loading guns of this calibre about to be supplied from Krupp's works will have the bore longer by 2½ calibres, so that the initial velocity communicated to the 496-pounder shot by a charge of 82½lb. of prismatic powder will be increased to about 1,360ft. per second. The gun was discharged, as we have said, by a vent through the wedge; but there was another vent on the top of the gun, which was closed by a steel screw, and was not used. The objects of the experiments were to ascertain the charge required to give a shot of 550lb. Russian (496lb.English) an initial velocity of at least 1,300ft.; to demonstrate by a trial of endurance that, with the charge thus arrived at, a Krupp 11-inch breech loader will stand a greater number of rounds than is required to render it fit for active military service. The trial took place in the presence and under the direction of Major General Majevski, Colonel Janowski, and Captain Doppelmair, of the Imperial Russian army.

With respect to the powder. experiments in for a breech-loader, and the new breech-loading

is required to render it fit for active military service. The trial took place in the presence and under the direction of Major General Majevski, Colonel Janowski, and Captain Doppelmair, of the Imperial Russian army.

With respect to the powder, experiments in Russia and at Essen had shown that the prismatic powder introduced into Russia some years since was yearly without an excessive strain on the gun, and the Russian Government, therefore, sent to account the Russian Government, therefore, sent to account the render of the factory had also a stock of prismatic powder made by Ritter, of Hamm, in Rhenish Prussia, according to the Russian formula. The cartridge bags were of single cotton stuff, the cartridge forming a regular single cotton stuff, the cartridge forming a regular hexagon, with tiers of 37 prisms; the greatest diameter of the hexagon being 965in, the smallest diameter of the hexagon being 965in, the smallest diameter of the hexagon being 965in, the smallest deak grow, it has a convenience for loading; the recoil was on an inclined plane, so that the gun, after each round, ran back nearly to its original position. It stood in a roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but at roofed place, and the firing was into an earth but a charge in the second was 32-9ft. from the muzzle; the second was 32-9ft. from the first. THE ROYAL INSTITUTION.

THE first meeting for the founding of the Royal Institution of which there is any record was held in 1799, at the house of Sir Joseph Banks, and the following letter from Faraday to Mr. Weld, contains all the particulars obtainable respecting its transactions:—

all the particulars obtainable respecting its transactions:—
"Royal Institution, March 20, 1848. My dear "Royal Institution, March 20, 1848. My dear Sir,—According to the earliest document I can find, the first meeting held for the purpose of founding the Institution, was March 9, 1791, at the house of Sir Joseph Banks, in Soho-square. It is called a meeting of the managers, and there were present—Sir Joseph Banks, the Earl of Morton, the Earl Spencer, Count Rumford, Richard Clark, Esq., and Thomas Bernard, Esq. These were the men; and at that meeting, they made Sir Joseph Banks chairman, and Mr. Bernard secretary. The title and purposes of the Institution as given at that time are as follows:—Institution for Diffusing the Knowledge and Facilitating the General Introduction of Useful Mechanical Inventions and Improvements, and for Teaching by Courses of Philosophical Lectures and Experiments, the Application of Science to the Common Purposes of Life. You will see that no idea of the research that grew up in the time of Young and Davy, entered into the conceptions of the founders. The first meeting of the proprietors (now replaced by those we call members), took place on April 20, of the same year. Ever truly yours, M. FARADAY.

[C. R. Weld, Esq."]

the research that grow up in the time of Young and Davy, entered into the conceptions of the founders. The first meeting of the proprietors (now replaced by those we call members), took place on April 20, of the same year. Ever truly yours, M. FARADAY.

C. R. Weld, Esq."

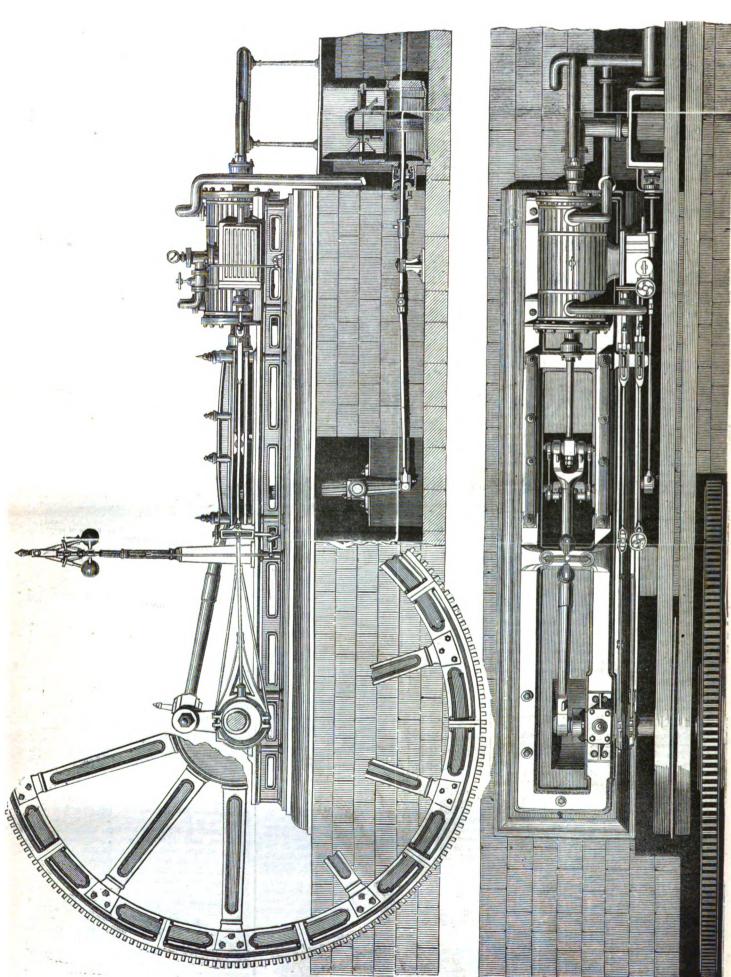

In the first days of the Institution, its supporters were divided into "proprietors, life subscribers, annual subscribers, and ladies," the whole being annual subscribers, and ladies," the whole being amalgamated by a somewhat complex constitution, which gave the "proprietors" hereditary rights, but permitted the shares of the other subscribers to be bought and sold in the open market. The first meeting of the proprietors was held on April 20, 1799; and in the following June, they took possession of some houses in Albemarle-street, to be used for the purposes of the Institution. The rooms were opened, and the lectures began in March, 180°. At the stime, and the lectures began in March, 180°. At the stime, and the lectures began in March, 180°. At the stime, and the lectures are present entertained. The objects of this society were then of a nature very different from those at present entertained. The commercial applications of science occupied the attention of the promoters more than the discovery and elucidation of natural laws. For instance, at march 31, 180°, after several rules had been passed, March 31, 180°, after several rules had been passed, they appointed fourteen committees for the following chees; 4, improving stoves; 5, improvements in making cheap bread; 2, improvements in making making cheap bread; 2, improving morter and emmert; for use in stoves; 11, improving mortar and emmert; 12, how to build houses of different kinds of earth, rammed together; 13, committee of mechanics; 14, rammed together; 13c committee of mechanics; 14, rammed together; 16 can be an authorised of

# STEAM FIRE-ENGINE FOR VALPARAISO.

STEAM FIRE-ENGINE FOR VALPARAISO.

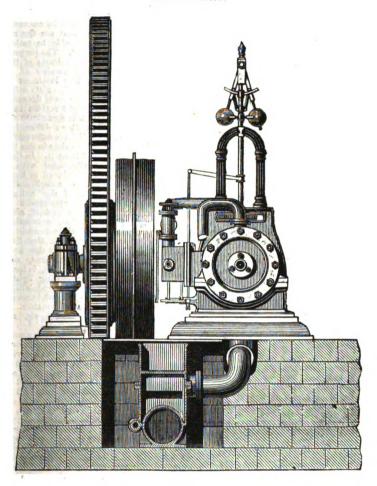

THE steam ship "Panama," which left Liverpool on the 13th inst., has taken out to Valpara so, for the No. 3 Fire Company there, one of Mes rs. Merry weather and Sons' largest size Admiralty pattern double-cylinder steam fire-engine, same as the engine "L'Empereur," one of those for which the firm received the gold medal at the Para Exhibition of 1867. This new engine, named "Cachapoal," is highly finished and deco ated, has a high-toned bell and whistle, and is ar any d to be drawn by the volunteers of the Company af creates the American style; it has two horizontal steats be drawn by the volunteers of the Company af er the American style; it has two horizontal stea t cylinders, each 83in. diameter, and two coubl-acting pumps, each 64in. diameter, with 24in. stroke of pistons, and a suction hose 64in. i.t. rnd diameter. Before leaving London it was not a constroke of pistons, and a section hose 6\(\frac{1}{2}\)in. Let rull diameter. Before leaving London, it was put o a thorough test, which proved highly satisfied ry. Mesers. Morryweather had previously supplied two other but smaller sized stoam fire-angines to the No. 1 and 2 Companies at Valparaiso, which have No. 1 and 2 Companies at Valparaiso, which have proved most efficient in subduing fires, and they now have a fourth steam fire-engine for the city of Santiago, which is within a few miles of Valparaiso, and where our readers may probably Valparaiso, and where our readers may probably recollect some three years ago a cathedral and many persons were destroyed by fire.

. FORTY-HORSE HORIZONTAL  $^{7}_{\rm J}$  CONDENSING ENGINE. BY M. BOYER.

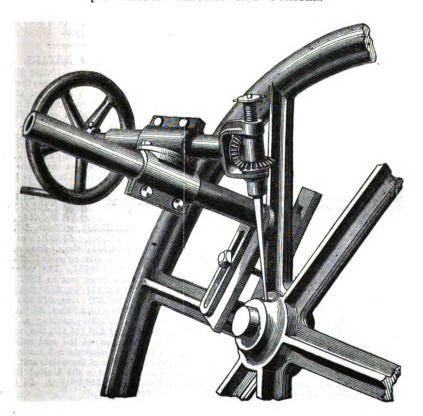

## FORTY-HORSE HORIZONTAL CONDENSING ENGINE.

END ELEVATION.

## PORTABLE DRILLING MACHINE.

BY MESSRS. WESTRAY AND FORSTER.

## HORIZONTAL CONDENSING ENGINE.

HORIZONTAL CONDENSING ENGINE.

THE profizontal engine illustrated herewith is a fine specimen of work which has been turned out from the factory of M. P. Boyer, of Lille. The general design of the engine, which is 40-horse power, horizontal condensing, with independent variable expansion, will be seen from our engravings. The cylinder is 28-29in. diameter, and the stroke 59in. The steam circulates from the boiler round the cylinder jacket, from whence it enters the main steam pipes just above the throttle valve, and is regulated by an independent valve. The piston rod is continued through the hinder end of the cylinder and protected by a sheath. The rod itself, with all the main working parts, are of steel. The flywheel is made in two sections bolted together. The box consists of three discs; in the centre one are recesses for the arms, which are double, and are bolted at each side of the rim, into which they also dovetail, and of the centre boss; the outer are bolted at each side of the rim, into which they also dovetail, and of the centre boss; the outer discs of the boss are then put on with countersunk headed screws, the outer surfaces being turned up bright. The fastening of the arms in the rim is very perfect, the mode of using a double arm taking the rim at each side gives a facility of securing the whole together like a sandwich beam. There are a double row of wood teeth in the ring of the flywheel, the section of which is formed to admit of the easy replacement of ways teeth from admit of the easy replacement of worn teeth from each side of the wheel. At the point where the arms grasp and are let into the segments of the arms grasp and are let into the segments of the rim the mouldings are filled in flush, giving thickness of metal for the open dovetail mortice in which they take. Motion for the air-pump, which is also horizontal, is taken by a beam from the crosshead. The air-pump has four india-rubber valves, and a very perfect vacuum is obtained in working. M. Boyer may be considered the founder of the mechanical arts at Lille, a city which is the Manchester of continental Europe Manchester of continental Europe.

## PORTABLE DRILLING MACHINE.

MESSRS. WESTRAY AND FORSTER, engineers, Barrow-in Furness, have introduced an excellent patent portable drilling machine, which is well worthy the notice of all our mechanical readers. It is a great improvement upon the ratchet brace, inasmuch as it will do four times the amount of work with only the same labour as the brace. It also possesses other advantages over the ratchet brace, as, for instance, drilling at any angle. as shown by our engraving. labour as the brace. It also possesses other advantages over the ratchet brace, as, for instance, drilling at any angle, as shown by our engraving, which represents the apparatus employed in drilling a hole at an angle which the ratchet brace could not get at. This tool is especially adapted for drilling or boring holes in any piece of work too heavy to be moved to an ordinary machine. The apparatus consists of an upright pillar, having a cranked base, and upon which a cast-iron movable bearing is clamped by screw bolts. The cranked base of this tool is shown in our engraving as made fast to the wheel upon which the drill is working. On the upper side of the bearing is a flanged face, upon which a similar flange turns, one face being recessed and the other being made with a projection. The upper bearing is made with a projection crossbar formed with a forked end, and which is free to revolve in the bearing. It can also be moved backwards and forwards in it, and is fixed in position by set screws. In the hollow crossbar is fitted a spindle which has a hardalso be moved backwards and forwards in it, and is fixed in position by set screws. In the hollow crossbar is fitted a spindle, which has a handwheel at one end, whilst at the other is fixed a bevel pinion gearing into a bevel wheel. This bevel wheel drives a spindle similar to an ordinary drilling machine, which slides within it, but by means of a long keyway, and fixed key in the wheel, is made to revolve with it. The drills are fixed in the spindle in the usual way, and the feed motion is imparted by a screw working through the forked end of the crossbar and receiving the end of the drilling spindle. By this arrangement it will be seen that the drill can be fixed so as to drill a hole at any angle and anywhere within range of the machine. It is exceedingly compact, and is self-contained, so that there is no loss of time in looking for the several parts. The whole apparatus weights only 100th, its size heing short aight times that contained, so that there is no loss of time in looking for the several parts. The whole apparatus weighs only 100lb., its size being about eight times that of the one shown in our engraving. This drill will be found specially useful for shipbuilding and marine work purposes. It has been well received by engineers generally, and is in use by many of our leading firms. In fact, it is just one of those useful tools which ought to be found on every bench. bench.

#### THE LUMINOUS SEA. (Concluded from page 29)

Concluded from page 29)

IN the month of September, 1865, I again visited Herne Bay, and frequently had opportunities of witnessing the luminous appearance of the sea. I caught many of the hemispherical and minute species of Medusa, but not one of the Beroe fulgens. I observed that these luminous animals always retreated from the surface of the water as soon as the moon rose. I found also that exposure to the daylight took away their property of shining, which was viewed by placing them for some time in a dark situation. In that season I had two opportunities of seeing an extended illumination of the sea, produced by the above animal. The first night in which I saw this singular phenomenon was extremely dark. Many of the Medusa hemispherica and the Medusa scintillans had been observed at low water, but on the return of the tide they had suddenly disappeared. On looking towards the sea, I was astonished to perceive a flash of light about six yards broad, extend from the shore for about the distance of a mile and a-half along the surface of the water. The second time when I saw this kind of light proceed from the sea, it did not take the same form, but was diffused over the surface of the waves next to the shore, and was so strong that for a moment I can'll can be a recovered at the result of the surface of the waves next to the shore, and was so strong that distance from to the shore, and was so strong that for a moment I could see my servant standing a short distance from me. He also perceived it, and called out to me at the same instant. On both these occasions the flash was visible for four or five seconds; and although I remained watching for a considerable time, I did not

was visiole for four or nve seconds; and although I remained watching for a considerable time, I did not see it repeated.

The following experiments which I made upon this subject, would lead me to make different conclusions from those of the preceding authors.

1.—A glow-worm was put into a glass of water, in which it lived nearly two hours, and continued to emit light as usual, until it died, when the luminous appearance entirely ceased.

2.—The luminous substance was extracted from the above-mentioned glow-worm, and from others killed in different ways; but it afforded no light.

8.—The sacs, containing the luminous matter, were cut from the bellies of living glow-worms, and shone, uninterruptedly, for several hours in the atmosphere; and after their light became extinct, it was revived by being moistened with water: some of these were put into water in the first instance, in which they continued to shine unremittingly for 48 hours. 48 hours.

48 hours.

4.—The luminous substance of a glow-worm was exposed to a degree of heat which would have been sufficient to inflame phosphorus, without increasing the brilliancy of its light; and further it could not be made to burn by being applied to a red-hot iron, or to the flame of a candle.

5.—A delicate thermometer was introduced among some living glow-worms, during the time they gave out much light; the temperature of the room being 69, the instrument rose to 75, 76, 77, according to circumstances as the warmth was reflected from the hand, or dissipated by the worm crawling over cold substances. The luminous according to circumstances as the warmth was reflected from the hand, or dissipated by the worm crawling over cold substances. The luminous portion of the tail, when very brilliant, appeared to raise the thermometer quicker than the other parts of the body; but it was not invariably the case. When shining strongly, I thought that the luminous rings communicated a sensation of warmth to the hand, but this was probably a deception, as the actual degree of heat was not sufficient for such an effect. It should, however, be mentioned, that in Templar's observations on the glow-worm, he said his feelings deceived him if he did not experience some heat from the shining of the insect.

6.—To satisfy myself how far the evolution of heat during the shining of glow-worms depended upon the life of the animals, I cut off the luminous portion of the tail from several living worms, and found that if the thermometer was applied to them immediately, it was raised by them one or two degrees; but after these parts were dead, although they continue to emit light, they produced no effect whatever upon the instrument.

7.—Some hemisphorical Meduse were put into a reconnection a small quantity of sea water and

7.—Some hemispherical Medusæ were put into a spoon, containing a small quantity of sea water, and held over a burning candle. As soon as the water became heated the Medusæ appeared like illuminated became heated the Medusæ appeared like illuminated wheels, the spots at the margin and centre alone emitting light; in which manner they shone vividly and permanently for about twenty seconds, when they shrunk and died, after which they were no longer luminous.

8.—Some of the same species were put into spirits; a strong and unremitting light was instantly given out, which issued from the central and marginal parts, as in the preceding experiment, and continued until they died.

9.—Some of the sciutillating and homispherical

9.—Some of the scintillating and hemispherical 9.—Some of the scintillating and homispherical species of Medusa, contained in a small glass jar, were introduced into the receiver of an air pump, and the air being exhausted, they shone as usual when shaken. If any difference could be perceived the light was more easily excited, and continued longer in a vacuum.

I wished next to try the influence of electricity on

the luminous property of animals.

10.—A Medusa hemispherica was placed in a small glass dish, containing a quantity of water,

merely sufficient to allow the animal to preserve its merely sufficient to allow the animal to preserve its figure; being insulated, it was electrified, and sparks drawn from it, which had not the slightest effect; the experiment was repeated several times with different individuals, but without exciting the animals to throw out light.

11.—Some hemispherical Meduse were placed in contact with the tree and set are interpreted being

of the animal.

contact with the two ends of an interrupted chain and slight electric shocks passed through them. During the very moment of their receiving the shock no light was visible but immediately afterwards the Medusæ shone like illuminated wheels, which appearance remained for some seconde. Upon the closest inspection with a magnifying glass, no contractile motion could be perceived to accompany the exhibition of the light. The application of electricity in this instance seems to have acted merely as a strong mechanic shock.

The above experiments on the luminous Medusa were made at Herne, with the assistance of George May, Esq., of Stroud House, and in the contact with the two ends of an interrupted chain

The above experiments on the luminous Medusa were made at Herne, with the assistance of George May, Esq., of Stroud House, and in the presence of a large company capable of accurately distinguishing their results. It seems proved by the foregoing experiments, that so far from the luminous substance being of a phosphorescent nature it sometimes shows the strongest and most constant light when evaluad from exagen gas that it is no sometimes shows the strongest and most constant light when excluded from oxygen gas, that it in no circumstances undergoes any process like combustion, but is actually incapable of being inflamed; that the increase of heat, during the shining of the glow-worm, is an accompaniment, and not an effect of the phenomenon, and depends upon the excited state of the insect; and, lastly, that heat and electricity increase the exhibition of light, merely by operating like other stimuli upon the vital properties of the animal.

of the animal.

In confirmation of these opinions, I may quote the high authority of the secretary of this Society, who has found that the light of the glow-worm is not rendered more brilliant in oxygen, or in oxygenated muriatic gas, than in common air; and that it is not sensibly diminished in hydrogen gas.

I may further add that Spallanzani's experiments of diffusing the luminous liquor of the Medusa in water, milk, or other fluids, are in direct contradiction of his own theory, as is also the extinction of the

water, milk, or other fluids, are in direct contradiction of his own theory, as is also the extinction of the light of these mixtures by the application of a high degree of heat. If the light emitted from animals were derived from their food, or the air they respire, as supposed by Carradori, the phenomenon should be increased or diminished, according to the quantity of food or air that the creatures consume; but we do not find this to be the case, for in those but we do not find this to be the case, for in those situations where they are sometimes found to be most luminous, they are deprived, in a great measure, of these assumed sources of their light.

of these assumed sources of their light.

In fact, the luminous exhibitions of living animals are not only independent of all foreign light, but are frequently destroyed by the latter. I have always found the shining of the Meduse to cease upon the rising of the moon or at the approach of day; and when out of the sea I never could excite them to throw out light until they had been kept for some time in the dark; all the luminous insects likewise secrete themselves as much as possible during the day time, and go abroad only at night. I have, it is true, found that the Scopolendra electrica will not shine unless it has been proviously exposed

during the day time, and go abroad only at night. I have, it is true, found that the Scopolondra electrica will not shine unless it has been previously exposed to solar light; but I have observed that it shoue as brilliantly and as frequently, after being kept a short time in a light situation, as when left uncovered the whole day, the circumstance of the Scolopendra requiring exposure previous to its giving out light, is very unaccountable, as the insect, when left to itself, always seeks as much as possible concealment during the day; indeed, it is the opinion of some naturalists that it is killed by the light of the sun.

The opinions of Brugnatelli and Carradori are connected with some general dectrines, respecting the nature of light, which I shall not at present venture to discuss. It appears to me, that the question is still unresolved, whether light has a substantial existence, or is a phenomenon depending upon certain operations or conditions of the ordinary forms of matter. But the highly ingenious researches of Count Rumford, on the law of what have been called subtle fluids, and the extraordinary advances lately made by Mr. Davy, on the decomposition of substances, that were hitherto looked upon as elementary, give us reason to hope that future investigations may unfold views of the material world, of which we can at present have only an indistinct conception: that now modes of analysis may enable us to see things, not "through a glass darkly" but more nearly as they are; and that the boundaries of physical and metaphysical science, now so far asunder, may be made to approach each other.

In the present state of our knowledge, our business

In the present state of our knowledge, our business should be to collect, arrange, and compare phenomena, rather than to speculate upon their nature. Nevertheless, I cannot refrain from observing, that the circumstances attending the luminous appearance of living animals, are much more favourable to the supposition of light being a property, than a substance. The quantity of light emitted by an animal in a certain time (admitting it be matter) far exceeds that which could be possibly anount was £41,712,880.

supposed to be derived. Thus the luminous appearance of some Medusæ may be continued with the intermission of short intervals for an indefinite the intermission of short intervals for an indefinite time, notwithstanding the creature be kept in dark-ness, and without any other food than what a small quantity of filtered sea water would afford. The uninterrupted and long continued light that is sometimes evolved by the luminous seas, and the ova of the glow-worm, is also inconsistent with the notion of an accumulation and subsequent dispersion

ova of the glow-worm, is also inconsistent with the notion of an accumulation and subsequent dispersion of a material substance.

I shall terminate this paper by an enumeration of the several conclusions, that are the result of the obrervations I have been able to make upon the phenomena of animal light. The property of emitting light is confined to animals of the simplest organization, the greater number of which are inhabitants of the sea. The luminous property is not constant, but, in general, exists only at certain periods, and in particular states of the animal's body. The power of showing light resides in a peculiar substance or fluid, which is sometimes situated in a particular organ, and at others diffused throughout the animal's body. The light is differently regulated, when the luminous matter exists in the living body, and when it is abstracted from it. In the first case, it is intermitting, or alternated with periods of darkness; is commonly produced or increased by a muscular effort, and is sometimes absolutely dependent upon the will of the animal. In the second case, the luminous appearance is usually permanent until it becomes extinct, after which it may be restored by friction, concussion, and the application of warmth, which last cause operates on the luminous matter (while in the living body) only indirectly by exciting the animal. The luminous matter in all situations, so far from possessing phosphoric properties, is incombustible, and loses the quality of emitting light, by being dried or much heated. The exhibition of light, however long it may be continued, causes no diminution of the bulk of the luminous matter. It does not however long it may be continued, causes no diminu-tion of the bulk of the luminous matter. It does not require the presence of pure air, and is not extinguished by other gases.

extinguished by other gases.

The luminous appearance of living animals is not exhausted by long continuance, or frequent repetition, nor accumulated by exposure to natural light; it is therefore not dependent upon any foreign source, but inheres as a property in a peculiarly organized animal substance or fluid, and is regulated by the same laws which govern all the other functions of living beings. The light of the sea is always produced by living animals, and most frequently by the presence of the Modusa scintillans. When great numbers of this species approached the When great numbers of this species approached the surface, they sometimes coalesce together, and cause that snowy or milky appearance of the sea, which is so alarming to navigators. These animals when congregated on the surface of the water, can produce a flash of light, somewhat like an electric corruscation. When the luminous Meduse are very numerous a feasing the season of the water is confined. corruscation. When the luminous Medusæ are very numerous, as frequently happens in confide bays, they form a considerable portion of the mass of the sea, at which times they render the water heavier, and more nauseous to the taste; it is therefore advisable always to strain s.a water before it is drunk. The luminous property does not appear to have any connection with the economy of the animals that possess it, except in the flying insects, which by that means discover each other at night for the purpose of sexual congress.

for the purpose of sexual congress.

## MINERALS AND METALS.

THE production of coal in the United Kingdom in 1867 reached 104,500,480 tons; that of the United States is said to be estimated at about 25,000,000 tons. Nearly one-fourth of the coal raised in the United Kingdom comes from the Durham and Northumberland coal-fields. There were 2,871 collieries in the United Kingdom in 1857, and 3,258 in 1867; in 1857 the entire production of coal from them was only 65,394,707 tons.
The following statement shows the value of the minerals raised in the United Kingdom in 1867: minerals raised in the United Kingdom in 1867:—
Coal, £26,125,145; iron ore, £3,210,098; tin ore, £624,784; copper ore, £699,693; lead ore, £1,158,066; zinc ore, £41,340; iron pyrites, £67,453; gold quartz, 3,241 tons, £5,320; nickel ore, £14; arsenic, £4,112; gossans, &c., £5,808; wolfram, £62; manganese, £3,232; barytes, £7,807; coprolites £70,300; salt, £836,963; clays, fine and fire £589,650; earthy minerals estimated £650,000 making a total of £34,169,797. The value of the  $\pounds$ 583,650; earthy minerals estimated  $\pounds$ 55,000 making a total of £34,169,797. The value of the metals obtained from these ores in 1867 was as follows:—Iron, £11,902,557; tin, £799,293; copper £831,761; lead, £1,337,509; zinc, £79,693; silver 895,394oz., £215,400; gold, 1,520oz., £5,890; other metals, estimated, £15,000; making a total of £15,000; (30,000) making a total of (30,000) ma £15,187,013. Adding £26,125,145, the value (at the place of production) of the coal raised, and £2,167,933 for other minerals not smelted, salt, clay, &c., the total value of the metals and coal and other minerals produced. other minerals produced in the United Kingdom in 1867 is found to be £48,480,092. In 1866 the

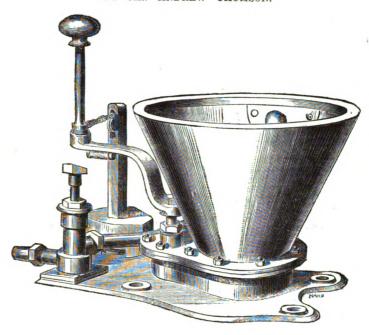

#### THOMSON'S PATENT SHIP WATER-CLOSET.

WE have much pleasure in introducing to notice a water-closet for ships' use, which is the invention of Mr. Andrew Thomson, of Southampton, who holds the position of foreman plumber to the Peninsular and Oriental Steam Navigation Company. The principle on which this water-closet is constructed entirely prevents all leakage and the return of effluvia into the ship after passing the valve, two points of paramount importance, as it is well known that the ammonia in urine forms a crust in the soil pipe, and so causes the offensive smell usually emanating from water-closets of defec-tive construction. On an inspection of the annexed engraving, it will be seen that the handle moves round in a slot cut in the seat. This opens a disc valve, and so cleans its face and at the same time flushes the basin; when the handle is let go, the valve returns to its place, leaving 4in. of water in the basin. The disc valve is worked by an upright the basin. The disc valve is worked by an upright spindle through a stuffing box packed with flax yarn and tallow, completely preventing all leakage from the outside. The supply valve is opened by the lever pressing on the cross-head, and is shut by means of a spring attached to the bottom of the valve; this prevents any waste of water. Twenty years' experience in ships' water-closets constructed on the old principle of pulling up the handle, and trials of every suggested method of curing these defects, all of which have more or less failed, have induced Mr. Thomson to bring forward his patent. We feel assured that it will be ward his patent. We feel assured that it will be found to answer its purpose better than any hitherto in use; in fact, we have numerous testimonials before us in favour of its efficiency.

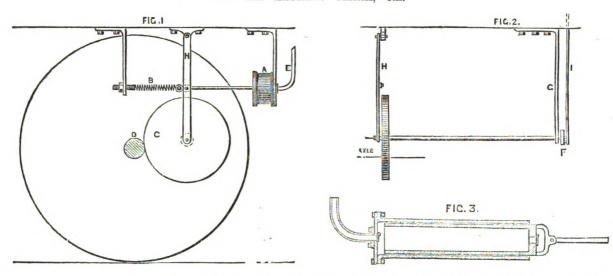

## PATENT SHIP WATER-CLOSET.

BY MR. ANDREW THOMSON.

#### INTERCOMMUNICATION IN RAILWAY TRAINS.

BY MR. LATIMER CLARK, C.E.

#### CLARK'S SYSTEM OF INTERCOMMUNICA-TION IN RAILWAY TRAINS

IN the early part of the year we described a In the early part of the year we described a pneumatic apparatus for signalling in railway trains, invented by Mr. Latimer Clark, C.E. This apparatus has been practically applied on the London, Chatham, and Dover Railway, a satisfactory trial having been recently made in the presence of some forty of the leading railway engineers of the kingdom. In this experiment, when the train was running at speed through a tunnel with the steam blowing off, communication between guard and driver was maintained with the greatest facility. The main feature of this system consists in the employment of powerful bells on the angine in the employment of powerful bells on the engine or tender, and in each of the guards' vans, actuated by the axles of the wheels, and which, therefore, unless thrown out of gear by an arrangement described below, continue to sound loudly as long as the train is in motion. The way in which they are kept out of gear, whilst it is not desired to give a signal, is by the employment of a pneumatic length of the train, being connected between the carriages by short lengths of flexible tubes. A small air-pump is attached to the engine, or to some other part of the train, and, as long as the latter is travelling, produces a partial vacuum (equal to about half a pound to the square inch in in the employment of powerful bells on the engine or tender, and in each of the guards' vans, actuated

the whole length of the tube. of the guards' vans and the te of the guards' vans and the tender a cylinder is fixed, in which a piston is acted upon by the partial vacuum, and throws the bells out of gear as long as the vacuum is maintained. It follows from this that when the train first moves, the bells begin to sound; but immediately afterwards a partial vacuum is produced, and all the bells are thrown out of gear, and therefore remain silent so long as the train continues in motion. If, however, any person, in any part of the train, opens a communication between the tube and the atmosphere, the vacuum is destroyed, and all the bells are brought at once into play, and continue to sound until the communication is reclosed again, or until the train stops. When the guard wishes to signal to the driver, or the driver to the guard, he does so by simply opening a cock communicating

Underneath each | riages and down the ends. The connections between the carriages are made by a short length of india-rubber garden hose. Over each passenger com-partment the tube is supplied with a T-piece, into the lower branch of which a plug is fitted, being connected by means of a chain with a knob or handle inside the compartment. The passenger handle inside the compartment. The passenger pulling down the knob removes this plug, and is prevented raising the handle again by a wedge falling within its shaft. The signal bells are of a size and strength suitable to the rough wear and tear and noise of a railway train. They are protected from dust and dirt by a strong perforated casing. They are struck by hammers, which receive direct motion from the train, and there is therefore no limit to the force which may be amtherefore no limit to the force which may be employed to set them in motion. The motion which

axle D, and thus stopping its motion and the ring-The gong is sounded by the light rod I, fig. 2.

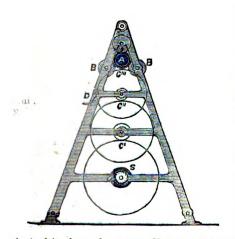

It is obvious that this system is capable of very various modifications. By employing the motion of the train as the source of power, there is, practically, no limit to the energy with which the signal may be given. The employment of a gong, as arranged upon the London, Chatham, and Dover Railway, has the advantage of giving a signal of a nature totally different from any of the other sounds produced by the engine or train. It is also found that a small independently working cylinder underneath the tender and guards van gives a sharp and intermittent whistle. The employment of a fog horn gives a still more powerful sound. But, whichever is the means of signal chosen, it is clear that the air forms a safe and cheap medium of communication, and the apparatus which it requires is little liable to disarrangement from accidental causes.

## ON WAR ROCKETS. BY MR. JAMES NASMYTH, C.E.\*

UNDER the impression that the improvement suggested in the following remarks upon the above-named subject may lead to important results when carried into effect, I have ventured to solicit the favour of the attention of the members of the Manchester Literary and Philosophical Society to the subject, in the hope that it may interest them, and by their kind favour be recorded in their transactions, and so place the suggested improvements in question at the service of the public. The valuable properties possessed by rockets as implements of warfare are so great, that could precision of flight be added, they would rise to a position of the highest importance as destructive agents.

The comparative lightness and portability of rockets, and the fact of their combining gun, charge, shot, or shell, all in one and the same projectile, together with their alarm-producing and highly-destructive properties, has (notwithstand-ing their wildness or uncertainty of flight) caused them to be employed in warfare in many instances with most effective and important results. It is with the object of giving to such rockets all the advantages of rifle action, and so securing pre-cision in their flight, that I desire to suggest means for effecting that important object by an agency that appears to me to be at once simple and effective.

Before proceeding to describe the means whereby I propose to effect the object in question, I would premise that what constitutes the true rifle principle in a projectile is not only the condition of axial rotation in the line of flight, but, above all, is the condition that the projectile possess the highest degree of axial rotation from the first in-

stant of its forward course. Unless this latter condition be present, no subsequent axial rotation, be it eyer so great, can correct a bias or unprecise flight after the flight has commenced. The grand desideratum to be sought for is, that at the instant the rocket commences its flight, it shall possess the highest degree of axial rotation. With such conditions present, we shall confer on our rocket all the properties (as regards precision of flight) of the most perfect rifle projectile.

It is difficult by words alone to convey a per-

fectly clear idea of the mechanical arrangement by which I propose to effect this desirable object. I

have therefore accompanied these remarks with an illustrative diagram of the mechanism by means of which I propose to confer on the rocket the requisite degree of high axial rotation, so that, like a true rifle projectile, it shall possess that indispensable condition of precision of flight from and at the very instant it sets out on its course. Before proceeding to describe the distinctive features of my contrivance for effecting the object in question, it may be as well to allude to the means that have been employed in the endeavour to secure to war rockets rifle action or precision of flight. These consist in placing the rocket in a V-shaped trough, by which the direction and inclination the rocket is suitably secured previous to com-mencing its flight, and so far holding the rocket fair in the direction of the object aimed at. Besides this, an endeavour is made to give the rocket axial rotation during its flight by causing the propulsive gases, while issuing at the rear of the rocket, to rush through skew holes. This latter arrangement does, to a certain extent, give to the rocket axial rotation. But, as axial rotation given by such means does not come into effective operation until the rocket has proceeded a long way on its course, it comes into action too late to have any influence in securing precision of flight.

In order, then, to effect our object, I place the

rocket inside a tube (into which it slides freely); to this tube, which serves to secure the aim of the rocket, I give, by mechanical means, an axial rotation of some thousands of revolutions per minute, which is transmitted to the rocket then resting within it. The rocket, while thus revolving on its axis at the high velocity above named, is then fired, and so rushes forth from its guide tube impressed with all the conditions of a perfect rifle projectile, and, as such, with every condition present that can secure its reaching the object aimed at. Reference to the diagram will enable the reader to obtain a clear idea of the mechanical means and arrangements by which I propose to effect in question. consists of a suitable iron stand, supporting the rocket and its guide tube A, the guide tube resting on loose friction wheels, which, while preserving with the utmost exactness the direction of the axis of the guide tube and rocket, permits the guide tube and rocket to revolve on its axis with all due facility. The requisite amount of axial rotation is conveyed to the guide tube and thence to the rocket resting within it, by means of a powerful clock spring S, transmitting its rotation to the rocket through the train of wheels C 1, C 11, C 111.

Previous to firing the rocket, the wheel C<sup>11</sup> is locked by the catch or trigger D; the spring S is then wound up, and the aim and elevation of the rocket adjusted. The match of the rocket is then lighted, and in order to secure energetic combus-tion of the rocket ere it is allowed to rush forth on its course, the rocket is held in check by three slight springs within the guide tube at the rear of the rocket, by means of which it is not permitted to rush forth until the proper energy of discharge of propulsive gases has been acquired. As soon as this is the case, the rocket frees itself and then rushes forth impressed with and possessing every condition of a true rifle projectile combined with all those important properties which rockets possess as implements of warfare.

#### THE RAINFALL IN CORNWALL.

THE following particulars relating to the rainfall in Cornwall during the past year are taken from a gauge 340ft, above sea level, and correspond more or less closely with four other registers in different parts of the county:—

		Da	ys on which
	Inches.	.01	or more fell.
January	 6.94		23
February	 2.64		22
March	 3.48		20
April	 3.80		13
May	 2.50		14
June	 0.84		7
July	 0.76		10
August	 4.03		20
September	 5.72		13
October	 6.20		22
November	 7.87		16
December	 9.56		30
W-4-1	7101		210
Total	 54.34		210

In 1867 the fall was 48.52, and there were 213 wet days. Average for last for five years, 49 13in. and 212 wet days. TRIAL TRIP OF THE "DECCAN."

ESTERDAY week the "Deccan," which is the most recent addition to the Peninsular and most recent addition to the Fennisular and Oriental Company's ficet, underwent an official trial in Stokes Bay. This fine vessel was built and engined by Messrs. William Denny Brothers of Dumbarton; she closely approximates in size and burden to the "Himalaya." Her principal dimenburden to the "Himalaya." Her principal dimensins are as follows:—Length between perpendiculars, 345ft.; breadth of beam, 42ft; depth of hold, solits; breath of beam, 42ft; depth of hold, 30lft; builders' measurement, 3,001; gross tonnage, 3,128. She is fitted with engines of 600 nominal horse-power (indicating 2,730 during trial), diameter of cylinders, 76in., and length of stroke, 4ft. She has a four-bladed propeller of 18ft. 10in. diameter, with a pitch of  $27\frac{1}{2}$  to  $30\frac{1}{2}$ , weighing  $12\frac{1}{2}$  tons. Two runs at the measured mile showed the following results:—1st Run.—Steam 25lb.; vacuum, 28in.; revolutions, 52; knots, 12-950. 2nd Run. 28in.; revolutions, 52; knots, 12·950. 2nd Kun.—Steam, 25lb.; vacuum, 28in.; revolutions, 52; knots, 14·516, the true mean speed being 13·733 knots per hour. There was a light westerly breeze blowing at the time, and the sea perfectly smooth; barometer, 30·39. The total weight of coals, water, stores, &c., on board was 1,256 tons, and the search of pretaining the search of the and the vessel's draught of water was 18ft. 5in. forward and 19ft. aft, the mean draught being 18ft. 8½in. The heating surface of the boilers is 12,504 square feet, firegrate surface 420 square feet, and condensing surface 5,864 square feet. On leaving Stokes Bay the "Deccan's" head was put to sea, and she ran round the Isle of Wight, steaming from the Warner Light (a stiff westerly breeze which was found to be blowing outside the Wight compelling her to run several miles out to sea) to the Needles in 2hrs. 35min. A sister ship to the "Deccan," to be named the "Hindostan," of 3,000 tons and 600-horse power, is building at Messrs.
Day and Co's iron works at Southampton, and will be ready for sea in August.

## THE SOLWAY VIADUCT.

THE Solway Junction Railway, which has been for several years in course of construction, is now so near completion that it is expected that next month an engine will be able to run over the entire line from Kirtlebridge to Brayton. The permanent rails between Kirtlebridge and the Solway Viaduct are laid, and the station houses are being erected. The viaduct, which is a fine being erected. specimen of engineering, is now finished. Between the English end of the viaduct and the shore an embankment is in course of erection. A line of temporary rails already connects the viaduct with the shore. Some difficulty has been experienced at Bowness Moss. The Moss is about two miles at Bowness Moss. The Moss is about two miles across. A considerable portion of it, however, was drained some years ago, and the remainder is now being drained, and it is expected that it soon will be sufficiently consolidated to carry the rails. The river Wampool is crossed on a viaduct of seven bays. The viaduct is similar to the one over the Solway. A bank of 500 yards connects the shore with the viaduct. The remainder of the line is in a forward state.

#### GRINDING CORN.

A STATEMENT has appeared in the "Journal of the Chamber of Agriculture" by which it appears that we have not yet profited by all the lessons that may be learned from foreigners, and we are far behind some of the continental nations in our methods of preparing our food. Chemists prove to us that the grain of wheat contains exactly the proportions of starch, gluten, fibrine, &c., best adapted for human aliment; but we persist in throwing to the lower animals all but the white inside, or if we try to obey the chemist we make loaves of whole meal—flour and coarse brown bran together—forming a compound that gives heartburn and indigestion to half those who partake of it. But in other countries people are wiser, says the "Journal." The great mills in Pesth have nine pairs of stones, one above another, each pair set to grind more finely than the pair next above, and so the wheat, entering at the top of the mill, is roughly broken by the uppermost pair of stones, divided more effectively by the second pair, more triturated by the third pair, still more by the fourth pair, more and more finely granulated by the fifth, sixth, seventh, and eighth pairs, and finally reduced to a soft powder—flour, sharps, shorts, and bran altogether—by the ninth and lowest pair of stones. The product is precisely conformable to the views of the chemist, and, in addition, makes itself delightfully agreeable, instead of irritating, to everybody's animal physiology. Mechanically ingenious, too, these mills are fitted with stones somewhat differing from those ordinarily seen in Eng-A STATEMENT has appeared in the "Journal of the Chamber of Agriculture" by which it appears

<sup>\*</sup> Corresponding Member of the Manchester Literary and Philosophical Society.

The eye or central opening is very large, so that all the grinding is done between the faces of the stones, far from the centre, and therefore (as reason would point out) where the motion of the runner is most rapid.

So far the "Journal." But Messrs. Chapman and

Co., of Hatcham Mills, referring to this statement, write as follows:—The English are not at all behind continental nations in this respect, as by our process we not only do all that the Pesth millers do, but we consider that it is done in a far superior manner. We have tried various methods, and find manner. We have tried various methods, and find that it is impossible to produce a good flour in the way pointed out, as the effect of grinding the bran with the flour so fine is to kill the flour (as the bakers express it), and thus produce a cake, instead of a light loaf such as is used in this country; besides the danger of rubbing off the faces of the stone by their close contiguity. By our process the flour is first separated; the bran is then ground to the same first separated; the bran is then ground to the same degree of fineness in iron machinery, and afterwards restored to the white flour. By this method we are able to produce a flour for the manufacture of bread free from millstone grit and all the coarser particles of bran, which in the usual way cause indigestion, diarrhoa, &c. Compared with white flour there can be no question of the superiority of this kind of flour, as in addition to the starch, we are enabled to utilize all the other constitutents of the grain—e.g., the gluten or flesh-forming principle, as well as the earthy and alkaline phosphates, for promoting the growth of the bones and teeth—all of which are required in our daily food, more especially in that of young children and the dwellers in large towns and cities.

#### EXPLOSIVE BULLETS.

THERE is a story told of a fat man who objected to fighting a duel with a shadowy antagonist, until his opponent, in the most liberal manner, offered to chalk a line, representing his own proportions, upon the person of the fat man, agreeing, at the same time, that anything which hit outside of that line was not to count. Of some such nature, says the U.S. "Army and Navy Journal," is the agreement recently entered into by the high contracting parties to the Anti-explosive Small-ball Convention, assembled at St. Petersburgh. The Convention, assembled at St. Petersburgh. The purpose of the convention was an amiable one; but where is the power to enforce its provisions? Wars are usually the result of violating treaties, and in what respect does this one differ from the innumerable what respect does this one differfrom the innumerable contracts between governments which have been made waste paper of as soon as interest opposed them? Henceforth, a soldier who is killed by an explosive projectile weighing less than 400 grammes (1402.), will have the satisfaction of knowing that the killing is illegal, and don't count. What more? If the European powers who sign this agreement keep it in case of war, they will do it, not because of the parchment they have put on file, but because the discussions of the convention have satisfied them that nothing is to be gained by the use of explosive bullets. It is fortunate that this conclusion has been arrived at, though we doubt whether a simple certification of this fact would not have answered every purpose of this parchment.

## THE NEW BRIDGE AT NIAGARA.

THE new suspension bridge which spans the Niagara River a short klistance below the cataract has been completed so far that it is passable for foot passengers. This structure, though not so cataract has been completed so far that it is passable for foot passengers. This structure, though not so massive and capacious as that built a mile and a-half below, is at once an object of marked interest. The width and depth of the chasm at this point rendered the construction of this work quite difficult, and makes it an object of attraction as a scientific achievement in the art of engineering. The dimensions of the bridge, as recorded in the "Buffalo Express," are:—The span from rock to rock is 1,190ft.; the span between the centres of the towers is 1,26sft. The length of the suspended platform is 1,240ft. Height above the surface of the river, 190ft. The length of the central portion resting on cables is 635ft. The length of the platform supported by stays and cables is 605ft. The deflection of cables at the centre—in summer, 91ft., and in winter, 88ft., making the rise and fall of the bridge from changes of temperature, 3ft. The length of the cables between the points of suspension in medium temporature is 1,286ft. The length of the cables between the points of suspension in medium temporature is 1,286ft. Height of towers above rock on Canada side, 105ft, and on American side, 100ft. Base of towers, 28ft. square, and top, 4ft. square. The surface of the rock on the American side is 5ft. above that on the Canada side. The height of the roadway above the rock on both sides is 7ift. The depth of the anchor pits below the surface of the ground is 18ft., and the length of the anchor chains under the ground is 30ft. The anchors are set in solid rock on the Canada side, and in masonry on the American side.

the parapets is 10ft., depth of side truss, 6ift., and height of parapet above floor, 4ift. The bridge is supported by two cables, composed of two wire ropes each, which contain respectively 133 No. 9 wires. supported by two cables, composed of two wire ropes each, which contain respectively 183 No. 9 wires. The weight of these wire ropes per lineal foot is 9lb., and the diameter of the cable is 7in. The total weight of the suspended portion of the cable is 82 tons net. There are 48 stays weighing 15 tons net. There are 52 guys connected with the bridge. The aggregate breaking strain of the cable is 1,680 tons net, and that of the stays 1,320 tons net, making the total supporting strength of the cables and stays 3,000 tons. The number of suspenders used is 480, with an aggregate strength of 4,800 tons. The weight of the suspended roadway, including weight of cables and stays, is 250 tons. The ordinary working load is 50 tons, and the maximum load is 100 tons; permanent and transitory load, 350 tons. The towers, when completed, will be covered with wood and corrugated iron, and in point of architectural beauty will be highly ornate, imparting to each terminus of the bridge an air of elegance and substantialness, and rendering the whole an attraction among the beauties and wonders of that interesting locality. On the opening of another season, when the roadway will be completed, it will be available for carriages. be available for carriages.

## Acgal Intelligence.

ROLLS COURT, CHANCERY-LANE. January 11. (Before the MASTER of the ROLLS).

DAW V. ELEY.

OUR readers will no doubt remember that an order was made in this cause, on the motion of Mr. Daw, the plaintiff, to commit Mr. Collette, the solicitor, of Lincoln's-Inn-fields, for contempt of Court, in writing and procuring to be published in the "Volunteer Service Gazette" three letters, under the signature of "Copper-cap," relating to the subject-matter of the suit, and alleged to be in part founded on the pleadings and evidence, with the view of influencing the result of the suit; but the order was not to be drawn up for a fort-night, so as to give Mr. Collette an opportunity of making an apology and paying the costs of the motion. A letter of apology, signed by Mr. Collette, had since been inserted in the "Volunteer Service Gazette" before the fortnight had elapsed. He had, however, declined to pay a bill of £62 for the plaintiff's costs of the motion, on the ground that it was excessive, and offered to refer it to any solicitor of eminence, but his offer was declined.

Mr. Russell Roberts, who appeared on behalf of the plaintiff, now moved the Court to enforce the order to commit Mr. Collette, on the ground that his apology was insufficient, and that the

plaintiff's costs had not been paid. His Lordship having read the letter which was inserted in the "Volunteer Gazette," thought it a sufficient apology. He had intended, when the case was before him, to say that if Mr. Collette would express his regret for having written the letters, and submit to pay the costs of the motion within a fortnight, no order would be drawn up. He could not make a fresh order to commit Mr. Collette, as he had submitted to pay the costs, which must be taxed in the usual way if the parties differed. All that he could now do would be to make an order that the costs should be taxed, and Mr. Collette pay them. He should give no costs of the present application.

## Correspondence.

COLOUR OF STARS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—It is a well-known fact, that in observing the so-called fixed stars through a telescope, they present themselves as mere specks of light, and it is impossible to discern any discal form. If, however, the telescope is lengthened, the stars appear to form discs of faint light. This is perhaps due to the circular form of the objective, as thus the disc is a reflection of the object glass. Giving a triangular form to the objective, one would see the stars, observed in the above manner, as small triangles. So far, the question of the form of the so-called false discs. I should, however, very much like to know if the discs of the coloured stars seen through a refractor of great power, in the above-monitoned way, send to the retina the same colour as that of the star. For example:—Eta Lyrae is a blue star; is the false disc blue also?—I am, Sir, yours, &c.,

Delft, January 9. Delit, January 9.

INVENTORS AND INVENTIONS.

INVENTORS AND INVENTIONS.

SIR,—Another inventor is dead. Mr. Chalmers, who for the past eight years has been urging upon the Admiralty, as well as the writer, the value of the cellular mode of constructing shield armour, and affixing it to the sides of ships of war, instead of the solid armour, which is so expensive, and causes ships of war to roll so much at sea. It is reported that Mr. Chalmers leaves a widow and family in very atraitmed circumstances, just as the second that Mr. Chalmers leaves a widow and family in very straitened circumstances, just as the second target ordered by the authorities was on the eve of completion for further experiments. Now, 'tis a fact that the former target in its resistive properties was greatly superior to any description of solid armour at the time tested: and the superiority of the cellular mode of constructing and affixing such built-up shield armour has been for some time admitted by all practical men. This mode of construction also fermed a part of the proceedings of the naval architects' meetings, held in the Society of Arts, carring 1867, in which discussion I took part, in connection with Mr. Scott Russell and other scientific practical men, upon which occasion it was scientific practical men, upon which occasion it was admitted that the construction of shield armour for admitted that the construction of shield armour for ships and fortifications, constructed upon what is called the girder cellular plan, and the interstices filled up with wood, would effectively absorb the effect of the blow from shot, and so be greatly superior in results to heavy solid armour plates. It is unfortunate Mr. Chalmers has now ceased to be with us in life to see the adoption of the plan, but such seems to be the general fate of all inventors. Many of them, which history proves, starve while they live, and are by many, far too many, looked upon as the pests of society, and treated as though they were impostors; and thus as the result, generally speaking, inventors die early—in other words, relly speaking, inventors die early—in other words, before the time comes when their inventions are duly appreciated, and themselves respected and rewarded.

How long is such a state of things to last? When

rewarded.

How long is such a state of things to last? When shall the manufacturing commercial classes, and especially the Government, awake up to and admit the fact that inventors and inventions form the basis of England's wealth and greatness—that proportionably as geuius is fostered, and correct inventions practically developed, just in the same proportion do we English hold the power, and make the way open to extending commerce and commercial prosperity. What shall the Tyne develope during the incoming year? Is there any latent plan undeveloped? Is the bituminous coal of Tyneside, and our counties of Northumberland and Durham, to go to the wall, so to speak, by Welch coal, because the bituminous coal makes smoke, which Welch coal does not? Are all the furnace plans failures, or is it the fault in the cause of mechanical connections which get out of order, or what? That's a question worth working, for the coal trade is bad in the districts referred to, and the fact is—that although the steam coal of this our district for steam generating purposes is better and cheaper, and in every respect superior to Welch coal, yet Welch coal is taking the steam coal trade, and the Hartley and other once steemed coals of this district have been put off the Admiralty list this year, and I know it as a fact that an order from the Turkish Government for coal for their ships of war has been given to Wales for Welch coal solely on account of the smoke which is emitted from the burning of bituminous coal.

What is to be done? It is simply this—let the steam coal trade agree to try some new plan by which their coals can and will be used in boiler furnaces, which plan does not specially depend upon careful stoking i.e., firemen or any jimcrack appliances, and then I will venture to predict there are

furnaces, which plan does not specially depend upon careful stoking i.e., firemen or any jimcrack appliances, and then I will venture to predict there are better times coming for our pitmen, sailors, steamship owners, but especially colliery owners; and this next year, if they lose no time, will at once prove the value of my plan, which is approved of by many practical men—whom I can refer the colliery owners to by name—will be a good new year, proving the fact that the steam coals of this district (Newesstle and Durham) are the cheapest and best in the world yet discovered for steam generating purposes, which I will personally undertake to prove weight for weight with coals. I will challenge such Welch coal in any properly constructed boiler furnace to generate as much steam as can be generated by supposed I am altogether personal, I suggest let the the steam coals of our localities. Less it should be supposed I am altogether personal, I suggest let the coal trade advertise for and agree to develope and adopt the plan which will enable the bituminous coals to be burnt without smoke and without mechanics. nical connections or the special attention of firemen.

—I am, Sir, yours, &c.,
London, January 12. G. BELL GALLOWAY.

On Monday last, the first compensation cases in reference to the new National Gallery came on before special juries, under the presidency of Mr. Under Sheriff Burchell, at the Sheriffs' Court, Red Lionsquare. The vicar and churchwardens of St. Martin's-in-the-Fields, for the library and school of Archbishop Tenison, were awarded £9,900, and the governors of the parochial school £7,500.

#### TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 ls. 8d. yearly, or 10s. 10d. half-yearly payable in

advance.
Alliterary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. B. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.
We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith, ED. M. M.
Advertisements are inserted in the MECHANICS' Magazine.

faith, ED. M. M.
Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type Special arrangements made for large advertisements.

Enquirer, M.—If you add 500deg, of heat to the 1,200deg already attained by the firebars, you will decidedly bring your bars down.

## Meetings for the Week.

Mon.—Royal United Service Institution.—Captain E. A. Inglefield, R.N., F.R.S., on "His New Hydraulic Steering Apparatus, as being fitted to H.M. Ship "Achilles." Licutenant Arthur H. Gilmore, R.N., Will Exhibit his New Expanding Plug for Stopping Shot Holes, and New Sponge for Artillery Practice, at 8.30 nm.

New Sponge for Artillery Practice, at 8.30 p.m.
Society of Engineers.—The President for 1869 will deliver his Inaugural Address, and also present the Premiums awarded for papers read during the year 1863. There will be a Ballot for the Election of New Members, at 7.30 p.m.
Tues.—Royal Institution.—Mr. R. Westmacott, on "Fine Art" at 2 p.m.

Tues.—Royal Institution.—Mr. R. Westmacott, on "Fine Art," at 3 p.m.

The Institution of Civil Engineers.—Renewed discussion upon "Mechanical Appliances for Getting Coal"; and, time permitting, a Paper will be read on "New Forry and New Brighton Piers," by Henry Hooper, Assoc. Inst. C.E., at 8 p.m.

Thurs.—Royal Institution.—Mr. Rupert Jones on "Protovan" at 3 p.m.

TRUEB.—Boysa Institution.—Mr. Herschel on "The Last Eclipse of the Sun," at 8 p.m.

SAT.—Royal Institution.—Professor Odling on "Hydrogen and its Analogues," at 3 p.m.

## Mabal, Military, and Gunnery Items.

THE steam fleet owned by the Peninsular and

THE steam fleet owned by the Peninsular and Oriental Company comprises a total of 48 oceangoing vessels, having an aggregate tonnage of 85,632 tons and 18,620-horse power.

It is stated that General the Hon. Sir Charles Gore, G.C.B., K.H., colonel of the 6th Foot, will succeed to the post of Lieutenant-Governor of Chelsea Hospital, vacant by the death of the late Field Marshal Sir Hew Dalrymple Ross.

The Viceroy of Egypt has deputed Colonel Muchir and Fingari Bey to visit France, England, Holland, Belgium, and Prussia in order to study the systems and implements of agriculture in the schools

systems and implements of agriculture in the schools of husbandry in those countries, and present reports

on the subject.

The "Monarch" is ordered to be fitted up with

THE "Monarch" is ordered to be fitted up with Gurney's gas apparatus, every portion of the vessel, between decks, being intended to be lighted by gas, which will be manufactured on board. The estimated expense of fitting up Gurney's apparatus is about £300.

SIR JAMES A. GORDON died this day week at Greenwich Hospital, of which he was governor, at the age of 86. This gallant and veteran officer was admiral of the fleet, and had served in the Royal Navy for the extraordinary period of 75‡ years. He was, we believe, the last survivor of Nelson's noble band of captains.

The guns in the park at Waterford were found on

THE guns in the park at Waterford were found or Monday morning to have been overturned from their carriages, and lying on the ground. They were restored to their former position in the course of the day by direction of the mayor. Nothing has been

day by direction of the mayor. Nothing has been ascertained of the perpetrators.

WE understand that Mr. Childers intends to effect the vast economy which will ensue by closing the Royal dockyards of Woolwich and Deptford with as little delay as will be compatible with the exigencies of the service. Two very important pieces of patronage which hitherto have been vested in the hands of the First Lord of the Admiralty will thus be abolished—these are the post of captain-superintendent of each yard. tendent of each yard.

A LETTER from Rome states that the Prussian Legation is taking earnest steps at the Vatican to obtain permission for the German soldiers of the Reformed religion in the Papal army to have the consolations of religion administered to them, when

needful, by pastors of their own form of belief. The number of Protestant combatants under the Ponti-fical flag is increasing every day, but all who die are invariably interred in the Roman Catholic

THE engines of the "Hercules," of the nominal power of 1,250-horse, and manufactured by Messrs. John Penn and Son, exhibited at the recent trial of the ship over the measured mile off Portsmouth an indicated power exceeding 8,500-horse, the greatest proportion of indicated to nominal power ever yet attained. The "Hercules" is ordered to make a six hours' trial at sea under similar conditions to those imposed upon the trials of the "Minotaur, "Warrior," and "Bellerophon."

"Warrior," and "Bellerophon."

THE wooden unarmoured screw frigate "Sutlej" is now having the last pieces of her machinery taken out alongside Portsmouth dockyard, preparatory to being taken into the breaking-up dock. It was only out alongside Portsmouth dockyard, preparatory to being taken into the breaking-up dock. It was only in October, 1860, that the "Sutlej" made her first speed trial as a new ship over the measured mile in Stokes Bay, when she attained a mean rate of speed of 13-076 knots per hour. She was then considered one of the handsomest and swiftest ships affect. She is now a striking illustration of the short life and costliness of a wooden-built ship of war.

In addition to the double screw iron armour-plated turret ship "Cerberus," just completed at the yard of the Palmer Shipbuilding Company, Jarrow-on-Tyne, for the defence of alelbourne, the Government

of the Palmer Shipbuilding Company, Jarrow-on-Tyne, for the defence of Melbourne, the Government has ordered two other armour-plated turret ships—the "Abyssinia" and the "Magdala"—to be constructed for the defence of Bombay, both vessels being built from the same drawings and patterns as the "Cerberus." We hear that the contract for building the "Abyssinia" has been taken by Messrs. Dudgeon, of Poplar, and that for the "Magdala" by the Thames Iron Shipbuilding Company, Blackwall.

Aninteresting meeting of the pilots of Liverpool was held yesterday week in the Bee Hotel, Queen-square, Liverpool. The occasion was the arrival at Liverpool of Mr. George Osgood, a pilot of New Orleans, who had been brought involuntarily across the Atlantic, owing to stress of weather, on board the ship "Expounder," of Boston (Captain Irvine), bound from New Orleans for the Mersey. An event such as this occurs at intervals of a few years, and the pilots at the port to which one of the same profession may be brought invariably treat him with the greatest hospitality. Tossts expressive of mutual friendship between the two countries were proposed and heartily received.

We are enabled, on the authority of the "Army and Navy Gazette," to state that there is no intention, and there never was any, of disbanding the Marines. The distinguished corps will continue to exist and be ready when called upon to maintain the high reputation which it has acquired, but in such reduced numbers as the altered state of the day demands. The reduction spoken of for the Royal Artillery would bring the arm in guns and horses very much to the state in which it was before the Crimean war. The troops and batteries would lose two guns each, and a corresponding number of

the Crimean war. The troops and batteries would lose two guns each, and a corresponding number of horses and men. However, no plan is yet approved

of definitively.

An old sailor, called Loubin, lately got away from An old sailor, called Loubin, lately got away from the galleys at Toulon. From the description of this gentleman, he seems to be exceedingly pictorial. He has on his right arm the bust of a woman, the bust of a man, a boat, and anchor, a savage, and a heart with a dagger in it; on the wrist a bracelet, on the hand a heart. On the left arm the bust of a woman, the name Adele, a woman, a dancing girl, two hearts with daggers, Louise, 1850, and a dove; on the wrist A, and a bracelet. On his chest two busts meant to represent the Emperor and Empress, and two doves holding a crown. On the right knee obseene designs. It certainly ought not to be difficult to reconize M. Loubin.

## Miscellanen.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending January 9, was 7,017. Total number since the opening of the Museum free daily (May 12, 1858), 1,476,326.

THE first All-England match of the year took place at Horsington, Lincolnshire, on Tuesday, January 5, and was won by Mr. Goodyear with one of Messrs. Ransomes ploughs against seven competitors.

A commission charged, on the proposition of the Royal Academy of Medicine, in Belgium, with an inquiry into the propriety of employing women in mines, has sent in its report, which expresses the opinion that females ought to be excluded from such unations

MESSRS. ROTHWELL, the contractors for the ere MESSRS. ROTHWELL, the contractors for the erection of the pumping engines at the Abbey Mills Pumping Station, have hitherto had the working of the engines, but as that duty will now devolve upon the Metropolitan Board of Works, that Board has appointed Mr. Usher, who has been engaged in superintending, under the direction of the engineer and assistant engineer, the erection of the machinery, to the effice of superintendent of the station. to the office of superintendent of the station.

THE commission appointed to select names

The commission appointed to select names of artists for the election of a foreign member of the Paris Academy of Arts, in the room of the late composer, Rossini, presented the three following:—Sir Edwin Landseer, R.A.; M. Dracke, Prussian sculptor; M. Dupré, also sculptor, of Florence. On the reception of the list, the Academy, according to custom, added other names—those of M. L. Gallait, Belgian painter; Signor Pietra Rosa, architect and archieologist, of Rome; and M. Geefs, the well-known sculptor,

In 1855 the number of silk looms at work in the canton of Zurich was 25,290, employing 32,862 weavers. During the most prosperous years of the silk trade, from 1858 to 1860, the number was 28,000, employing 37,000 weavers. Since then there has been a great falling off in this manufacture, and in 1867, though more active than the preceding years, the total number of silk looms was only 18,276, employing 26,883 weavers; and, although this trade is gradually improving, it will be many years before it regains its former prosperity. The total value of silk stuffs manufactured during 1855 was 8,291,406f., and in 1867 it amounted to 7,279,810f.

The tunnel under the Chicago river, known as the Washington-street Tunnel, connecting the south and west divisions of the city by a solid and permanent roadway, has just been completed, and was opened to the public on New Year's-day. The contract price was 328,500 dollars. The length of the work is about 1,605ft.; of the retaining walls of the open approach on the west side, about 320ft, and 275ft on the east side. The length of the main archway, or covered way, is 932ft. There are three archways leading through the tunnel; one is for foot passengers, and two for teams and horses.

Of the 4,141 miles of railways open in Prussia in

archways leading through the tunnel; one is for foot passengers, and two for teams and horses.

Or the 4,141 miles of railways open in Prussia in 1866, 1,959 miles, or nearly one half, are under State management. The Prussian Government is therefore now managing (without taking any account of the railways in the annexed provinces) 1,959 miles, although the State originally constructed only 1,061 miles so that State management has been extended

although the State originally constructed only 1,061 miles, so that State management has been extended to 897 miles constructed by private companies. In the whole of Germany, including Prussia, the preponderance of State management is still greater, the number of miles worked by the different States being 5,142, and only 3,840 miles are worked by companies. ENGLISH machinery is being largely employed by the natives of Siam. The Siamese dockyards are busy building and repairing steamers; iron bridges have been erected over some of the creeks; gas works constructed in the palaces of the king and prime minister; two steam dredges put together and set to work; and another steam rice mill added to the four large mills already existing. A large sugar mill and distillery; a saw mill; British ship-yard and drydock, have been in operation since the beginning of 1867; and as the supplies for all these come almost entirely from England, there must be a very considerable export of British machinery going on to the East.

THE imports of raw cotton into France, in the first THE imports of raw cotton into France, in the first nine months of 1868 amounted to 87,806 tons, as compared with 82,552 tons in the corresponding period of 1866. The United States sent France 40,102 tons to September 30, 1868, as compared with 35,974 tons in 1867, and 40,691 tons in 1866 (corresponding period). The imports of cotton into France from the United Kingdom to September 30, 1868, as 12,655 tons in 1866. 1868, amounted to 13,651 tons, as compared with 19,080 tons in 1867, and 33,984 tons in 1866 (corresponding periods). British India sent France 11,672 sponding periods). British India sent France 11,672 tons of raw cotton to September 30, 1868, as compared with 9,067 tons in 1867, and 7,080 tons in 1866

(corresponding periods).

A MICHIGAN paper reports the discovery of a gigantic human skeleton in a rock near the Sank Rapids. It says:—"The head is massive, measures Rapids. It says:—"The head is massive, measures 31½in, in circumference, low in the os frontis, and very flat on the top. The femur measures 26½in, and the fibula, 25½in, while the body is equally long in proportion. From the crown of the head to the sole of the foot, the length is 10ft. 9½in. The measure round the chest is 59½in. This giant must have weighed at least 900lb, when covered with a reasonable amount of flesh. The petrified remains, and there is nothing left but the naked bones, now weigh 304½lb. The thumb and fingers of the left hand and the left foot from the ankle to the toes are gone, but all the other parts are perfect. Verily, there were giants in those days!

all the other parts are perfect. Verily, there were giants in those days!

THE announcement that in Canada illuminating gas has been successfully produced from petroleum refuse has created much interest in this country; but it would be desirable to learn the character of the refuse employed. It is stated that by sending a stream of air, by means of an air-pump, through a cask of petroleum refuse, it becomes charged with vapour from the petroleum, and burns with the brilliancy of ordinary gas. Without some further description it can only be supposed that the refuse used is the light and more volatile constituents. If Mongreul, described some years since in the Mongreul, described some years since in the "Mining Journal." If it be not the more volatile constituents, the invention is impracticable, as the air will not act as a carrier to the vapours to a sufficient extent to give it a commercial value.

# Patents for Zubentions.

#### ABRIDGED SPECIFICATIONS OF PATENTS

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprictors of this Magazino. Other papers are hereby warned not to produce them without an acknowledgment.—

2065 T. B. Hodde, Adam-street, Adelphi, Use of hydro-carbonaceous fluids. Dated June 27, 1868.
The documents relating to this invention are with the law officers under objection, and therefore at present cannot be seen.

not be seen.

2066 B. WARRY, Gillingham, Kent. \*\*Breech-leading frearms. Dated June 27, 1863.

This invention consists in certain improved combinations and arrangement of mechanism in the construction of breech-loading frearms, in which central-fre ammunition is employed. The details of the invention are voluminous.—Patent abandoned.

minous.—Patent abandoned.

2067 J. Baggs and F. Brary, Camberwell, Surrey. Extraction and condensation of ammonia. Dated June 27, 1863.

The first part of this invention consists in blowing atmospheric air or carbonic acid or other gas capable of carrying the ammonia forward through a solution of ammonia contained in a close vessel, and then causing the air or gas so charged with ammonia to blow or pass through a metallic or saline solution, capable of arresting the ammonia, and of being decomposed thereby, and so forming the various ammoniacal salts. In the second part of the invention, a partial vacuum is formed, and used instead of pressure by means of a bellows, force pump, or other suitable contrivance adapted to the purpose.—Patent completed.

pleted.

2052 C. MATHER, Sulford. Eccarating or loosening and removing soil, &c. Dated June 27, 1868.

This invention consists in the application of a jet of water under pressure for loosening and removing soil and other deposits from the beds of rivers or other places where excavations are required.—Patent completed.

2059 J. Bowker and J. Ivers, Chowbent, Leigh, Lancashire. Replacing on the line of rails of metals, engines, tenders, &c. Dated June 27, 1868.

Luncashire. Explacing on the line of rails of metals, engines, tenders, &c. Dated June 27, 1868.

This invention consists in the application, adaptation, and construction of certain apparatus, which the inventors call slips. They construct these slips by preference of wrought-iron plates, and from each slip of two inclined planes, which embrace the rail on both sides, one inclined planes, which embrace the rail on both sides, one inclined plane being on each side of the rail, and the two being connected together across the top of the rail. These slips are used in pairs, one on each rail (they being made right and left hand), and are formed of the shape of the letter V, with flanges on each side to guide the wheels of the engine or other carriage. These slips are likewise furnished with points or guards to guide the wheels directly on to the rail. The engine or carriage being brought contiguous to the rails, it is drawn up the slips, by which action it is at once placed thereon in its proper position for work.—Patent abandoned.

2070 J. TYSON, Sparkbridge, near Ulverstone, Lanca-nire. Machinery used in the manufacture of bobbins. Dated June 27, 1868.

June 27, 1863.

This invention has for its object the roughing or forming the blocks from which to manufacture bobbins, and the boring such blocks at one operation, which the inventor effects by means of a tubular saw, having a revolving and reciprocating motion applied thereto, so as to pass along or through a block of wood held in position by a toothed instrument. Inside the tubular saw, and advancing therewith, is a boring bit, so as to bore a hole through the centre of the block, at the time the tubular saw is forming the outside thereof. The block is removed, and another is advanced and pressed to the toothed instrument above mentioned by means of weights, and held there until traversed by the tubular saw and boring bit, as above described—Patent abandoned.

2021 G. McCullock, Manchester. Thread polithing

2071 G. MCCULLOCH, Manchester. Thread polishing machines. Dated June 27, 1868.
This invention consists in the application of thread polishing machines of improved solf-acting spreading motions, for laying the threads side by side on the rollers,

instead of by hand as at present, and in an improved self-acting arrangement for giving the required tension to the threads on the rollers.—Patent completed.

acting arrangement for giving the required tension to the threads on the rollers.—Patent completed.

2072 W. F. DEANE, Farnworth, near Bolton. Obtaining oxide of manganese. Dated June 27, 1868.
Under one process, the inventor takes the residual still liquor of the manufacture of chlorine, and conveys it into a strong closed vessel containing carbonate of lime, and thereby evolves carbonic acid gas. The said carbonic acid gas is led by a pipe or pipes through a Cowper's or other furnace, and heated to the required temperrure. The heated carbonic acid gas is conducted into another strong vessel containing neutralized still liquor. The said neutralized liquor is agitated by the carbonic acid gas as it enters, and is also thereby subjected to the heat and pressure necessary to cause the desired reaction, and effect the transformation of the chloride of manganese has been converted into a carbonate of manganese. When the chloride of manganese, and this can be ascertained by the disappearance of the chloride from the supernatent liquor of the carbonate of lime, and it is removed and washed and heated in contact with the atmosphere, in accordance with a well-known reaction to convert the carbonate into oxide of manganese. Should the residual still liquor not contain unfficient acid, hydrochloric acid of greater strength can be added; in many works, weak acids from the condensing towers can be utilized for the purpose.—Patent abandoned.

towers can be utilized for the purpose.—Patent abandoned.

2073 H. Large, Notting-hill, London. Machinery for making bricks. Dated June 27, 1868.

This invention relates to that class of brick-making machinery which is employed to make hard bricks, and especially those which do not require burning. In carrying out the invention, the materials of which the bricks are to be made, when properly mixed, are placed in a mould, which is then brought under a plunger worked by a crank, pin, eccentric, or other equivalent mechanica-device, whereby the materials in the mould will become consolidated and compressed into the form of a brick. The mould with the compressed brick therein is then earried forward to a second plunger, the rod of which is connected by a rocking lever to the rod of the first plunger, so that immediately after a brick has been compressed, the brick that has just been passed forward will, by the descent of the second platon, be forced out of the mould into a receiving table attached to the end of a weighted lever, from which the finished brick is removed by hand, and then the table is carried up by the weighted lever into its original position, ready to receive another brick—Patent completed.

2074 G. H. Wilson, Sherwood-street, Golden-square,

lever into its original position, ready to receive another brick—Patent completed.

2074 G. H. WILSON, Sherwood-street, Golden-square, London. Apparatus for holding or winding tape measures, &c. Dated June 27, 1863.

This invention mainly consists in the arrangement in a case or holder, as hereafter described, of two wheels, two pinious, a roller which receives the measure, and a barrel containing a spring. The barrel is fixed, and contains a recoiling spring, having for its centre an arbor which has on the pivot, working just free of the barrel cover, a wheel driving a pinion, to which is affixed another wheel driving another pinion. This second pinion forms the axis of the roller, on which the measure is wound, having for its working centres a hole in the top of the inner case, and a hole in the barrel arbor. The case or apparatus is provided with a check action, consisting preferably, of a spring and ratchet wheel, the spring having a nib or pawl, and is fixed on the inside of the inner case, so as to lock or take into the teeth of the ratchet which revolves with the roller as the measure or band is drawn out. A spring with a projecting nut or finger-piece is fixed on the upper end of the inner case, and, when this nut is pressed, the locking apring is forced out of the ratchet teeth, the wheels being thus immediately relieved, and the measure or band being caused, by the action of the ratchet teeth, the wheels being thus immediately relieved, and the measure or band being caused, by the action of the ratchet teeth, the wheels being thus immediately relieved, and the measure or band being caused, by the action of the spring barrel, to fly back, and wind upon the roller.—Patent completed.

caused, by the action of the spring barret, to by cack, and wind upon the roller.—Patent completed.

2075 J. Morris, Middlesborough, York. Steam boilers. Dated June 27, 1868.

This invention has for its object an increase in the power and efficiency of boilers, particularly, for instance, those of the vertical class, and is especially adapted for those that receive the products of combustion from puddling or heating furnaces, and are known as stack boilers. The patentee uses an inner tube or flue extending from the top to the bottom, and through which the products of combustion pass. This tube is enlarged towards the lower part, forming a chamber, which he prefers should be a conical one, the apex of the cone being downwards, and the base being made convex upwards. Across this chamber, a table, by preference of cylindrical form, is fixed, which should be large enough to admits aman's body, and planted upon this cross tube is a saddle or chamber forming part of it, and the shape of which corresponds to the shape of the conical chamber around and above it. From the inner chamber to the outer one extend tubes, by preference of a conical or cylindrical form. These tubes, which may be eight in number (or more or less if desired), are arranged at about equal distances apart, all round the chamber, and he prefers that they should radiate outwards with the larger ends upwards. The outer shell of the boiler has at least two manholes, one in the upper part of the boiler, and another just opposite the cross tube aforesaid, in order to gain entrance to it. There are various modifications.

Patent completed.

Patent completed.

2076 R. SMITH, Islington. Preenting the fouling of iron and other thips bottoms. Dated June 27, 1868.

The inventor places a pipe along each side of the keel, stem, and stempost of the ship to be protected. These pipes he fills with a compound generating or producing a strong gas or vapour, capable of destroying barnacles, animalcule, or other animal or vegetable life liable to foul the ship's bottom. The gas escaping through perforations provided in the above mentioned pipes mingles with the air in the surrounding water, and, by destroying all animalcules in the vicinity of the ship, effectually prevents the fouling of the bottom. The ingredients of which the composition above mentioned is composed, are as follows:
—Sulphur, resin, and fish or other oil, in about equal proportions. For resin, raw turpentine or pitch may be substituted, if desired. The above ingredients are mixed together by heat, and are reduced to a plastic mass, with which the pipes are completely filled.—Patent abandoned.

2077 W. C. STIFF, Birmingham. Breech-loading frearms

2017 W. C. STIFF, Birmingham. Breech-loading frearms nd ordnance. Dated June 27, 1868.

These improvements have reference to breech-loading frearms, in which a sliding plug or closer is employed for

opening and closing the breech. The improvements consist, first, in making the opening at the top of the breech chamber or shoe through which the cartridge is introduced into the said chamber in the following manner:—The inventor makes the said opening of a length about equal to one-half the length of the cartridge, and the front part or end of a breadth equal to the diameter of the fore part of the cartridge, the rear end of the said opening being made of a diameter somewhat greater than that of the rim of the cartridge. In introducing the cartridge it is held in an inclined position, the projectile end being highest. The base of the cartridge is introduced into the rear end of the opening, and the cartridge prossed backwards, until the projectile or fore end falls into the breech chamber. By the pushing home of the sliding plug, the cartridge is pushed forward to its place in the barrel. When self-consuming cartridges are employed, no extractor is required, but when metallic cartridges or cartridges the cases of which require to be extracted after discharge are employed, the uses an extractor which withdraws the cartidge by its rim. In order to remove the extracted case from the breech chamber or shoe, he employs the arrangement constituting the second part of his invention. The improvements consist, second, in making, on the under side of the breech chamber or shoe, an opening nearly equal in length to the case of an exploded cartridge. The said opening is situated at the rear end of the said breech chamber or shoe, its front end approaching, but not being quite under, the rear end of the opening at the top of the said opening is situated at the rear end of the said breech chamber or shoe, its front end approaching, but not being quite under, the rear end of the opening at the top of the said breech chamber the enthefore described. When the cartridge case has been withdrawn from the barrel by the extractor, and is brought over the said opening, the weight of the base of the said case causes the front end to

chamber than when it is rigid.—Patent abandoned.

2078 W. B. LAKE, Southampton-hulldings, Chancery-lane. Apparatus for dycing textite fabrics. (A communication). Dated June 27, 1868.

The patentee claims, first, subjecting the articles or substances to be dyed to a process whereby the oxygenation of the materials is effected in a continuous automatic manuer. Second, dyeing in an open vessel under the pressure of steam, substantially as set forth. Third, the rotating cylinder enclosed in the tank, and constructed and operating substantially as and for the purpose set forth.—Patent completed.

2079 G. HANNAH, Haughton-le-Skerne, near Darling-ton. Fluid meters. Dated June 27, 1863.

The nature of this invention consists in the combination of a piston working segmentally to and fro in an annular chamber with a double piston working in a section of the same annular chamber, or in a straight line; also in the arrangements and construction of pistons, valves, and indicators applicable thereto. The invention is not de-scribed apart from the drawings.—Patent completed.

scribed apart from the drawings.—Patent completed.

2080 J. WARDMAN and J. and F. Baldwin, Sandbeds,
near Bingley, York. Steam botters. Dated June 29, 1863.

The object of this invention is to construct a steam
boiler occupying less room than horestore, for a given
amount of horse power, together with a more rapid circulation, and a greater heating surface and larger steam
space than any boiler of equal length and diameter constructed on the Cornish or other known principle.—Patent
abandoned

2081 W. BANTER, D. WARING, and J. S. WOOLER, Bradd. Apparatus for drying textile fubrics. Dated June 29,

2081 W. BANTER, D. WARING, and J. S. WOOLBE, DIRECTORD. Apparatus for drying textile fabrics. Dated June 29, 7868.

This invention consists in the construction and use of apparatus for the purposes set forth, comprising a series of metal pipes connected together in sets, forming grated platforms of shelves arranged in tiers one above another, either fixed or movable, and so that steam, water, or air may circulate therein, and may be enclosed (or not) in a room or chamber for air to be forced or drawn through them when used for drying rags, fabrics, or fibrous substances, or immersed in the liquid when used for heating cooling, and evaporating the same.—Patent completed.

cooing, and evaporating the same.—Fatent completed.

2082 R. SHAW and J. CLAYTON, Higher Walton, near
Preston. Looms. Dated June 29, 1863.

This invention relates to the yarn beam and weighting
motion of the loom, and consists in improved modes of
suspending the beam by the yarn for the purpose of causing the beam and yarn upon it to act as a weight for
weighting the yarn and keeping it at its proper tension.—
Patent completed.

2083 H. JEWITT, Leighton-road, London.

2033 H. Jewitt, Leighton-road, London. A new toy, in the shape of a mortar or spring gun. (A communication). Dated June 29, 1868.

This invention relates to a new toy in the shape of a mortar or spring gup, and consists in constructing the said mortar or gun so that, on pulling a string attached to the mortar, and by turning a central spindle passing through the gun, a ball or other article is projected at a great velocity from the muzzle of the said mortar or gun.—Patent abandoned.

great velocity from the muzzle of the said mortar or gun.—Patent abandoned.

2034 A. V. Newton, Chancery-lane. Liquid meters. (A communication). Dated June 29, 1863.

These improvements in liquid meters relate to the use of two double-acting cylinders, two pistons, and two valves with corresponding parts, the whole so arranged that the valve or valve stem belonging to the one cylinder and piston forms the guide for the other piston, and moves with it, and vice evrs. The pistons thus arranged are packed with elastic rolls. The invention also includes a new balanced sleeve valve and a new and improved mode of transforming the reciprocating motion taken from the moving parts into the rotary motion given to the registering apparatus. It also combines the advantages of a double crank meter without its disadvantages, and the moving of the valves directly by the pistons. Also the use of a crank shaft, thus arranged for moving the registering wheels, and also a mode of forming the fluid-tight joints of the valves by means of rubber rolls, which cheapens their construction, and admits of the passage of impurities without injury.—Patent completed.

2085 C. E. Brooman, Fleet-street. Apparatus for bleach-

2085 C. E. BROOMAN, Flect-street. Apparatus for bleachag or lixiriating fabrics and skeins. (A communication).
ated June 29, 1868.
The object of this invention is the construction of a

bleaching or lixiviating apparatus, with continuous circu-lation and pressure. The essential feature is the employ-ment of a lift, rotary, centrifugal, or other description o-pump, placed either outside or inside the bleaching vessel —Patent completed.

2086 G. H. Wilson, Sherwood-street, Golden-square, London. Watches, &c. Dated June 29, 1863.

This invention consists, first, of a new mode of, and mechanism for, winding: and, second, of a new mode of, and mechanism for, setting or adjusting the hands; and, third, of a new mode of, and mechanism for, adjustment to equalize the force of the mainspring, which mechanism also prevents overwinding. Reference to the drawing is to a full description of the invention.

2087 C. E. BROOMAN, Fleet-street. Manufacture of shawls, dc. (A communication). Dated June 29, 1868. This invention consists in a particular manufacture of shawls in imitation of embroidered or figured Indian shawls, which shawls can be made of the weight of ordinary French shawls and lighter than Indian shawls. For nary Frence snaws and ignier than indian shawls. For this purpose the patentee employs only one warp for the fringes for the ground, and to connect the wefts on the right side and on the reverse side, then he uses another and thicker warp which forms the design only, and is never employed in the body of the fabric. It is this colour warp working in a reverse manner to that of the wefts which is the chief feature of the new shawl, and which it the appearance of a figured Indian shawl .- Patent

2088 W. R. LAKE, Southampton-buildings, Chancer

2088 W. B. LAKE, Southampton-buildings, Chancery-lane. Apparatus for generating fand burning the vapour of naphtha. (A communication). Dated June 29, 1868. This invention relates to an apparatus for cooking and similar purposes, which is heated by burning gas or vapour produced from petroleum, naphtha, benzine, or other inflammable liquids, which gas is mingled with the vapour of water and with atmospheric air at the time of combustion.—Patent completed.

2089 F. J. Drechnler, St. John's Wood. Boilers and funaces, &c. Dated June 30, 1868.

The patentee uses a number of superposed heating surfaces proceeding from the furnace or flre, and carrying the heat through the same in a scrpentine or zig-zag course. The bottom of the furnace he would, in some cases, construct of an inverted funnel form, but the form must depend upon the particular use for which the same may be required. The door can be hinged so as to completely enclose the furnace or stove when for horticultural, domestic, or similar purposes, allowing the apparatus to assume the character of an open grate when desired, and he prefers to have a fuel feed-hole at top with a lid or cover, which may be made to fit into a trough containing sand-water, or other liquid, to hermetrically seal the same An extra chimney should be provided for the better carrying off smoke and gases, and such extra chimney should have its exit in the ordinary chimney at a point above the damper. There is much dotail.—Patent abandoned. doned.

2090 G. GLOVER, Pimlico. Apparatus for the combustion apphtha. Dated June 30, 1868.

of naphtha. Dated June 30, 1868.

In the burning of naphtha, benzole, and similar liquids, it is desirable to have a ready means of regulating the amount of wick exposed above the wick tube. For this purpose the inventor forms the outer tube capable of sliding on the wick tube, and of rising above that tube. When the wick tube is surrounded by another tube disass or other matter representing a candle, he forms the apparatus with a socket to admit of the lower portion of such outer tube sliding thereon to an extent corresponding with the extent of adjustment which may be desired at the upper portion thereof—Patent abandoned.

2091 G. BOWER, St. Neot's, Huntingdon. Boilers for

2091 G. Bower, St. Neot's, Huntingdon. Boilers for heating purposes. Dated June 30, 1868.

This invention consists in an improved construction of boiler for heating water for buildings, conservatories, and other purposer. The boiler is constructed of loose or independent cast-iron tubes, placed either vertically or horizontally, and fitting to each other by plain face joints so as to form water-tight junctions, the circulation being effected by arranging the ends of the tubes so that they communicate one with the other, without requiring circulating boxes or receptacles for the tubes. It is evident that a boiler of any magnitude may be readily constructed by bolting a number of these separate tubes together. The form of tube preferred is of a triangular section with cylindrical ends, but tubes of any other section may be adopted. These boilers may be enclosed in sheet-iron or cast-iron cases, or set in brickwork.—Patent completed.

Patent completed.

2092 J. RANALL and W. R. CRABB, Battersea. Carriage to be impelled by the manual action of passengers. Dated June 30, 1863.

This invention relates to the construction of a carriage capable of being propelled by a manual action of the passenger or passengers without the use of cranks, levers, or treadles, and consists, principally, in transmitting rotary motion to the driving axle by means of an endless chain, belt, or band passing round a toothed or grooved (or toothed and grooved) pulley keyed on the driving axle, and round a similar pulley attached to a disc or wheel provided with a handle or handles, and placed within easy reach of the passenger or passengers.—Patent abandoned.

2098 J. BLOMFIELD, Colchester. Sewing machines. Dated

ine 30, 1868.

The stands or tables for sewing machines should be The stands or tables for sewing machines should be made in motal, and they are to have three or more legs. Their rims or tops should be circular, or approximately circular, and a segment of a rim or top should be firmly affixed or be in one piece with each leg, and the regments are to be lapped and bolted together. In the rim and other parts glass may be inserted with the view to increase ornamental effect. The legs can, if desired, be brought together in the centre, and be secured by means of branching parts, on to which caps are fitted at top and bottom of such parts, screw bolts or nuts being used to tighten or draw these caps together, thus fastening the legs in positions. The working parts of the sewing machines, such as flywheel and the like, may be suitably connected to the legs or other part of the table or stand.—Patent completed.

2094 M. BERRO, Manchester, and O. Hopwood, and W.

ELAM, Liverpeol. Apparatus to be employed for numbering and printing tickets. Dated June 30, 1868.

The patentees claim a novel and peculiar arrangement and combination of mechanism described, or any slight modification thereof, whereby an arrangement of spirally composed type will be enabled to continuously print consecutive numbers or subject matter upon continuous length of paper, together with the arrangement of cutters for subdividing such continuous length of paper, as described, set forta, and fully illustrated in the drawings.

—Patent completed.

2095 J. H. BANES Kantaland.

described, set forta, and fully illustrated in the drawings.—Patent completed.

2995 J. H. Banks, Knutsford, Cheshire. Constructing buildings. Dated June 39, 1863.

That whereas, under ordinary circumstances, walls are built of wood, stone, brick, or other material of sufficient thickness and strength to bear and resist the weight and thrust of the floors and roof, the inventor, by the use of iron buttress standards, placed at defined distances apart, do merely relieve the walls of the weight and thrust, which standards have flanges formed upon them, so arranged that the spaces between one standard and another can be filled in with bearding, bricks, and bond timber, rubble, or any other material, as may be desired; and, further, that, upon the upper extremity of the standards, a shoe is formed to receive the end of roof principals, on one side of which shoe is formed of a separate plate, which manner of construction, allowing the woodwork to be belted tightly up to the side of the shoe, which is a part and parcel of the principal, thus making the attachment of the principal to the standard inthoroughly secure; and, further, the standard is provided with a projecting hook to receive brackets for supporting spouts, and a slot to receive the wall plates, which wall plate is used to tie the standards laterally to each other, as well as to receive the spars; and, further, the wall plate forms the transom of the windows, if desired. The bottom part of the standard is shaped as a bed plate (which may be botted down to a sill formed of wood, iron, stone, or brick, if necessary), and is further provided with a vertical flange, to which flange are botted joists that are sufficiently long to go across the building to be attached to the standard on to the opposite side; and, further, that instead of using iron boxes to receive the purlins, he uses iron back plates, which have this advantage, that they cenable him to attach the purlins to the purlins, he uses iron back plates, which have this advantage, that they cenable hi

2096 A. M. CLARK, Chancery-lane. Breech-loading fire-rms and cartridges. (A communication). Dated June 30,

2096 A. M. CLARK, Chancery-lane. Incon-locating prearms and carbridges. (A communication). Dated June 30,
1858.

This invention consists, first, in a mode of cocking the
gun during the act of loading. Second, in the employment of a spring striker for producing a more powerful
blow than can be obtained by a spring which is cocked
or put in tension by the hand without the aid of a lever.
Third, in so enclosing the striking parts as to prevent the
admission of dirt or matters which might impede their
action. Fourth, in obtaining a perfectly gas-tight joint
by means of a non-metallic cartridge of this invention.
Fifth, there is no cartridge case to be extracted after the
discharge. Sixth, the breech-closing and striking
mechanism is always preserved in a serviceable condition.
Seventh, the breech-closing plug is deprived of any part
requiring renewal from wear. Eighth, the breech-loading
firearms of this invention may be readily adapted for
firing and extracting metal cartridge cases. Ninth, in the
application in the latter case of an improved extractor for
withdrawing metallic cartridge cases, or cases with metal
ends. The invention is not fully described apart from
the drawings.—Patent completed.

2097 W. Daalish, Wellington Quay, Northumberland.

2097 W. Daglish, Wellington Quay, Northumberland. Kilm. Dated June 50, 1868.

This invention is not described apart from the drawings.

Patent completed.

2098 G. ALDER, Newcastle-on-Tyne. Screw propellers. Dated June 30, 1868.

Dated June 30, 1888.

This invention consists in imparting to the screw propeller a compound motion, consisting of a rotary motion with the shaft on which it is mounted, and also a rocking or sculling motion produced by continually changing the angle of the propeller blades with the axis of the longitudinal shaft. To this end the boss of the propeller, instead of being keyed firmly and immovably on the shaft, is connected therewith by a cross pin, on which it is capable of being made to rock while the shaft rotates. The rocking motion of the boss on its cross pin is effected by means of a crank or eccentric motion derived from the main driving shaft, and imparted to the boss or sleeve shaft, which is made to slide to and fro on the propeller shaft, and is connected by a pair of rods to the boss or arms of the propeller.—Patent completed.

2099 B. Ward. Newwastle-upon-Type. Machinery for

arms of the propeller.—Patent completed.

2099 R. Ward, Newcastle-upon-Tyne, Machinery for spinning or twisting tobacco. Dated July 1, 1885.

In forming rolls of tobacco twist the patentee employs reels so constructed that when the roll of tobacco twist has been formed upon it, the reel may be taken apart and the roll removed from it in the form required for sale. In the case of brown twist, or twist which does not require to be pressed, provision is made for tying and securing the roll before removing the reel; and, in the case of black twist requiring to be pressed, the reel is adapted to admit of the twist being pressed whilst upon the reel, the ends of the reel being capable of yielding to the pressure, and moving inwards, or towards each other, as the twist between them is consolidated. The end of the reel may have letters, or a pattern recessed into it, in order to mark, in a similar way, the roll which is pressed upon the reel.—Patent completed.

2100 J. Ward and W. S. Black, King's Lynn. Ma-

pressed upon the reel.—Patent completed.

2100 J. WARD and W. S. BLACK, King's Lynn. Machinery for twisting tobacco. Dated July 1, 1863.

The patentees claim, first, arranging machinery for twisting tobacco in such manner that a core of tobacco leaves, in connection with spinning or twisting apparatus, may be pieced or made up by a workman at a suitable table, and may then have covering leaves of tobacco applied to it, and lapped around it with a more rapid spiral, the amount of twist on the core and the length of the spiral of the covering leaves being under the control of the workman, and regulated by the amount by which

he checks the rotation of the core. Second, compressing a core of tobacco leaves by a reciprocating mallet or pressing instrument, at or near the spot at which covering leaves are applied to it. Third, the arranging machinery for twisting tobacco, substantially as described.—Patent expendent. completed.

2101 W. BROOKES, Chancery-lane. Rolary steam engines.
(A communication). Dated July 1, 1868.

This invention is not described apart from the drawings.

Patent completed.

2102 W. BROOKES, Chancery-lane. Electro-magnetic silvesy brakes. (A communication). Dated July 1, 1888. This invention is not described apart from the drawings. Patent completed.

2103 W. BROOKES, Chancery-lane. Meters for measuring ater, &c. (A communication). Dated July 1, 1868. This invention is not described apart from the drawings.

2104 Provisional protection has not been granted for this.

2105 C. F. CRAILSHEIM, Southampton-buildings, Chan-ery-lane. Bottles for efferescing liquids. Dated July 1,

The patentee claims, first, a bottle containing effervescing or gaseous wines or liquids constructed with two orifices one of which is provided with a syphon, substantially as set forth. Second, a stopper for champagne bottles, and other vessels attached to the neck of the same, an imade capable of being hermetically scaled and locked, substantially as set forth.—Patent completed.

2106 A. TAYLOR, Birmingham. Necktics or crasses.
Dated July 2, 1863.
These improvements consist in so arranging the tie or cravat that the parts that come together in the front shall be provided with worked or other eyeletted holes or apertures for receiving the shank of the improved fastener, which may be formed of bone, ivory, pearl, metal, or other suitable material, having an expanded or flat termination at its inner end, and so fashioned at the front end of the shank that a stud or other attachable ornament may be secured in, on, or otherwise attached to it.—Patent abandoned. Patent abandoned.

2107 A. ALEXANDER, Belvidere, Kent. Carriages and locomotive engines. Dated July 2, 1868.

The details of this invention are too voluminous to admit of our quoting them here.—Patent abandoned.

admit of our quoting them here.—Patent abandoned.

2108 L. Francis, New York. Compositions applicable to printing purposes. Dated July 2, 1868.

The nature of this invention consists, first, in combining glue and glycerine with or without saccharine matter to form a composition for printing purposes, other than printers inking rollers, where elasticity is required. The invention relates, in the second place, to a combination of glue and glycerine, with or without saccharine matter, with any of the metals, or their insoluble compounds, finely divided, or with the solutions of their soluble salts, for the purpose of manufacturing emery cloth, artificial homes, and stereotype plates, to be used by hand or by machinery, various forms of belts, wheels, for polishing, and for various purposes where an elastic composition is available.—Patent completed.

2109 H. H. HENSON, Parliament-street, Westminster. Rai'way wayyons and trucks. Dated July 2, 1868.

2109 H. H. HENSON, Parliament-street, Westminster. Rativary arapyons and trucks. Dated July 2, 1868. The patentee claims means whereby the body or superstructure of a railway waggon or truck is constructed separate from the under framing, and is so suspended or supported therefrom or thereby, or from or by parts fixed to the under framing, that the body shall be capable of more or less free end motion relative to, and independently of, the under framing.—Patent completed.

more or less free end motion relative to, and independently of, the under framing.—Patent completed.

2110 W. Dean and B. Andrew, Derby. Apparatus imployed for stopping the loom upon the breaking of the west turndord from the state. The improved machinery or apparatus is applicable to looms for weaving clastic webs, ribbons, fringes, or other narrow fabrics. In the improved machinery or apparatus a wire is used; at one or both selvages of each breadth of fabric made in the loom each such wire is secured to a rocking lever, at or near the centre of this lever, which lever has one of its ends inclined at its top side, and pointing inward towards the batten of the loom; the point end of the incline points slightly upwards at such times as the unbroken weft thread or threads press upon it, but when either weft thread is broken, the inclined end of the lever is depressed by its own weight, and, while so depressed, a reversely inclined piece of iron or other metal secured to the batten slides upon the incline of the rocking lever, thus elevating the outer end of the lever, which raises an arm secured to a rocking shaft, and on this rocking shaft is also secured a eatch lever, which takes into a catch, or slides by the side of a boss, or its equivalent, either of which is secured upon the hand rod, or its equivalent, there is the own, which throws the driving strap from one pulley to the other; the arm on the rocking shaft being raised, the catch lever will be thrown out of the catch, or clear of the boss on the hand rod, or its equivalent, leaving such hand rod, or its equivalent, free to be moved, so as to throw the driving strap from the fast pulley on to the loose pulley, and thus stop the foom. The rocking shaft which carries the lever and catch lever lies in bearings upon the lowerside of part of the front framing of the loom, and the hand rod, or its equivalent, leaving such hand rod, or its equivalent, every lies in bearings upon the lowerside of part of the front framing of the loom, and the hand rod, or its

moved clear of the above-mentioned caten of boss.—Fateus completed.

2111 J. D. PINFOLD, Rugby, Warwick, Apparatus for making bricks, tiles, &c. Dated July 2, 1868.

These improvements embrace the lubrication of the moulding oritices, and the pressing rollers of the apparatus (or some of them) and the surfaces (or some of them) of the compressing chamber or place where the squeezing takes place, with oil, water, steam, or other lubricant: also the construction of, and adaptation to the apparatus of, checks or scrapers, which may be at, to, or near to the oriflees, and of rollers in or partly forming the compression chamber, such checks, and the surface of such rollers, being of porous material, or semi-porous or non-parts of them, being movable and adjustable, if desired, to any dimensions required; also, when the compression chamber and die is formed with horizontal and vertical rollers, the adaptation of an adjustable or fixed upper, and an adjustable or fixed lower, plate or plates therein or thereof, lying generally horizontally, horizontal, or nearly

so. Further, the improvements embrace the construction of the compressing chamber, orifices, dies, rollers, and plates, wholly (in one or more places, as may be found convenient, of blue lias clay), Ransome's patent stone terra-cotta, wood, perforated or louvre fashload metal, on the notice of the notice of the property of the prope ierra-cotta, wood, perforsted or louvre fashioned metal, or other porous or semi-porous material, sqitably formed hold or receive lubricating matter if desirable; and with reference to cutting the expressed clay or material individual properties of the invention embraces the causing a folding cutter or divider to travel with the clay during the action of cutting or dividing, and so that it may be returned to its normal positions, all without stopping the sappeasing action; also the mechanically diving the carrying bands or rollers for receiving and carrying forward the clay as delivered from the ordices by or from the motion of a cutting wheel, such as the "Rugby" brick machines, including, also, application of friction arrangements, and of change wheels for varying speed. The invention comprises many other features, a description of which we cannot give space to here.)—Patent completed.

4112 J.E. POYNTER, Glasgow, and J. L. PATTERSON, Greenock. Manufacturing salipetre. Dated July 2, 1863
This invention has for its object the manufacture of salipetre directly, with ultimate recovery of the iodine and bromine, from kelp, seaweed, charcoal, or other residue of the decomposition of seaweeds by heat.—Patent

2113 E.J. SCOTT, Glasgow. Ornamenting boots and shoes.
pated July 2, 1868.
This invention consists in printing with enamel or japan
varials on the patent or enamelied leather.—Patent com-

pased.

2114 F. A. PAVEY, Peckham Ryc, Surrey. Marking bard for billiards, &c. Dated July 2, 1868.

The features of novelty which constitute this invention, consist, first, in so constructing marking boards so that the score cannot be set back, and thereby tampered with, and, second, that a considerably higher number can be scored than heretofore.—Patent abandoned.

2015 D, Hall, Winsford, Cheshire. Construction of furnaces. Dated July 2, 1868.

The improvements which constitute this invention relate more particularly to furnaces for salt pans, but may also be applied to steam boiler ond other furnaces generally. The object of the invention is in whole or in part to dispense with firebars and the ordinary grates, and to make provision for feeding the said furnaces with fust by mechanical appliances, and thus to save the manual labour consequent from the ordinary plan of construction and mode of feeding by a shovel, or other similar means.—Patent completed.

2114 IR Graggen Catashand Durham. Production of

2116 J. B. Gregson, Gateshead, Durham. Production of sulphate of lead. Dated July 2, 1863,
This invention consists in obtaining a sulphate of lead by decomposing a solution of chloride or muriate of lead by means of a solution, either of sulphate of soda, or of sulphate of magnesia, or of sulphate of iron, or by means of a mixture of sulphate of soda and sulphate of magnesia in solution—Patent abandoned.

in solution—Patent abandoned.

2017 E. PAVY, London-street, London. Treating and preparing certain vegetable and animal fibres to manufacture a new description of fabric or stuff applicable to various useful and descrative purposes. Dated July 2, 1868.

The patentoe claims, generally, the combination of processes or operations described for treating and preparing the fibres referred to, with the object of producing a sort of paper pulp, and of manufacturing from this pulp a felied paper, fabric, or stuff applicable to various useful and decorative purposes. And he claims, specially, submitting the fibres to what he calls the second were ling in caustic alkali after the gasoous chlorine. The details of the invention are voluminous—Patent completed.

of the invention are voluminous—Fatent completed.

2118 D. FENDER, Berwick-on-Tweed. Thrashing machines.
Dated July 2, 1868.

This invention consists, essentially, and particularly under one modification, in making four or other number of longitudinas, angular, or spiral rows of short tapered pins or teeth projecting nearly radially at intervals across the surface of the beating and stripping drum, by preference formed of malleable cast iron, in one piece, with their stripping bars screwed or otherwise secured to the drum at regular intervals round its circumference; these pins, teeth, projections, or rubbers (which may be of a round, elliptical or other sultable section), work within grooves or recesses of nearly the same depth as the height of the pins formed on a segmental part of the hollow casing round the drum close to and above or below the usual feeding rollers, according as the drum is driven up or down from them, the grooves having obtuse, angular, or curred radial ridges undulating round their sides or edges, by proference formed of projecting ribs cast on the inside surface of the segmental part, which is made to oscillate on a joint or axis near the feeding rollers, set at a proper distance from the pins or rubbers, to allow of the heads of the corm or crop entering and being carried round the grooves by the pins, so as to strip off the grain by rubbing on (the surface and edges of either or both sides of the radially redged grooves.—Patent abandoned.

2119 A. M. Clark, Chancery-lane. Barometers, &c. (A communication). Dated July 2, 1868.

ali P A. M. CLARK, Chancery-lane. Barometers, &c. (A (communication). Dated July 2, 1868.

The index does not indicate whether the pressure is stationary or on the increase or decrease, the object of the invention being to obtain this indication by adapting to barometers and other pressure gauges an additional part or solf-acting in-liteator to show whether the pressure is increasing or decreasing.—Patent completed.

2120 A. M. CLARE, Chancery-lane. Preparation of flax, temp, jule, 4c. (A communication). Dated July 2, 1868.
This invention consists in the production of threads from short staples instead of from the long fibros hitherto suployed.—Patent completed.

2121 A. F. ROBERTSON, Bedford-square, London. Carts.
Dated July 2, 1863.
This invention relates to devices for elevating the forward end of a laden cart when descending an incline, in order to relieve the back of the beast by throwing more of the load upon and behind the arle, and also to devices by which such apparatus is made to act in unison with a brake upon the wheels.—Patent completed.

2123 J. H. JOHNSON, Lincoln's Inn-fields. Shoes for the de. (A communication). Dated July 2, 1868.
This invention has for its object the more effectually

securing the shoes of horses and other animals to the foot, whereby the nails ordinarily employed for that purpose are dispensed with, and the shoe is better enabled to resist any shock or strain to which it may be subjected, and consists in interposing between the hoof of the animal and the shoe an adhesive substance, the base of which is either canotchouc or gutta percha, and which firmly unites the shoe to the foot.—Patent completed.

firmly unites the shoe to the foot.—Patent completed.

2123 J. H. JOINSON, Lincoln's Inn-fields. Construction of bridges. (A communication). Dated July 2, 1888.

This invention relates to a method of constructing bridges, whereby the temporary framework or scaffolding ordinarily employed to support the main structure during the progress of the work is dispensed with, and consists, mainly, in the use of two or more levers projected from the opposite sides of the spaces to be spanned, and meeting in the centre, each lover being composed of a series of superposed layers, and each layer extending a certain distance in advance of the one immediately below, thus increasing by so much the projection of the lover.—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT.

Dated January 5, 1869.

23 H. A. Bonnevillo, Suckville-street, Piccadilly. A new and improved process for conting all sorts of urticles with gold, silver, and other metals or mixture of such metals as may be beaten into thin sheets or contings. (A communication).

metals as may be beaten into thin sheets or coatings. (A communication).

24 L. Hannart, Kinz-street, Clerkenwell, Mid llesex, Improvements in the manufacture of printers' type, numerals, and other characters and devices in metal or compounds of metal, such as embossing blocks and other ornamenting tools used by bookbinders; also crests, monograms, seals, endorsing stamps, and numbering, dating, and alphabetical wheels used in stampling and endorsing machines employed for various purposes.

25 S. Bateman, Asuiere, near Paris. Improvements in paddlewheels.

26 W. Prosser, Lancashire. Improvements in the purification and bleaching of oils, gums, and resins and spirits.

27 E. W. and J. Voce, Salford, Lancashire. Improvements in the construction of rotary fans.

28 E. Fox, Sheffield. Improvements in the manufacture of all descriptions of metallic iron and steel worked in paddling furnaces.

ing the same.

30 J. Balbirnic, Fernley-place, Sheffield. A new or improved apparatus for inhaling vapours, medicated air,

improved apparatus for inhaling vapours, medicated air, or gases.

31 J. H. Johnson, Lincoln's Inn-fields. Improvements in sowing machines applicable to other machines worked by foot power. (A communication).

32 A. Mason, Craven-street, Strand. Improvements in the distillation of bydrocarbon oils. (A communication).

33 G. Smith, Manchester. Improvements in transces for the consumption of smoke.

34 D. Nicoll, Cornhill, City. Improvements in the construction of clothing for male and fomale use, and in the method of manufacturing materials to be employed therein.

therein. 35 W. Dawes, Kingston-grove, Leeds. Improvements in

36 S. Remington, Southampton-buildings, Chancery-lane. Improvements in breech-loading firearms.
37 A. W.C. Williams, Bridgeport, Fairfield, Connecticut, U.S.A. Improvements in lawn mowers. (A communication)

tion).

38 J. Stovens, Southampton-buildings, Chancery-lane.
An improved machine for platting, tucking, or folding, and dividing linen and other textile fabrics.

Dated January 6, 1869.

39 H. L. Vallee, H. A. Dourlet, and A. M. H. Armand, Boulevart, Sebastopol, Paris. Improvements in the manufacture of artificial flowers and foliage from vegetable parchment.

Boulevart, Sebastopol, Paris. Improvements in the manufacture of artificial flowers and foliage from vegetable parchment.

40 J. S. Gibsorno, Liverpool. Improvements in mechanical telegraphs.

41 E. Robbins, Stibbington-street, Somers Town, Middlesex. Improvements in the manufacture of decorative and perforated or tubular casts, slabs, blecks, or other forms and in the application thereof to the construction of buildings and other purposes.

42 K. Walter, Wicklow. Improvements in the manufacture of sulphuric acid.

43 A. Tyler, Mark-lane, City. Improvements in articles known as bon-bons or co-sacks.

44 W. Pidding, Walcot-square, Surrey. Improvements in the method or methods of treating plants, shrubs, and vegetable productions, for the purpose of extracting, collecting, and preserving the aroma and volatile matter or essential oil yielded by them.

Dated January 7, 1869.

45 G. Eveleigh, Tredegar-road, Bow, Middlesex. Improvements in the manufacture and purification of gas for righting, and in the means of applying the same to heating purposes, parts of which improvements are also applicable to the purification of mineral oil.

46 J. Mansergh, Westminster Chambers, Westminster. Improvements in stonch traps.

47 J. F. Cooke, Camnon-street, City. Improvements in the manufacture of copying luk.

48 H. Davey, John-street, Adelphi, Middlesex. Improvements in apparatt for raising and injecting water, and for feeding boilers.

feeding boilers.

49 F. N. Gisborne, Wost Strand, Middlesex. Improvements in means or apparatus for giving motion to sewing and other machines.

ments in means or apparatus for giving motion to sewing and other machines.

50 F. R. A. Glover, Bury-street, Middlesex. Improvements in the means of, and apparatus for, letting down, weighing, and fishing ships anchors.

51 J. H. Johnson, Lincoln's Inn-flelds. Improvements in the preparation of concentrated food tablets or cakes. (A communication).

52 W. Webster, Dundee, Forfarshire. Improvements in treating and softening jute, hemp, flax, and other fibrous substances, and in the machinery or apparatus connected therewith.

53 J. J. Bodmer, Newport, Monmouthshire. Improvements in the manufacture of iron and steel.

54 H. G. Fairburn, Goswell-road, Middlesex. Improvements in machinery for compressing and solidifying coal,

clay, lignite, peat, and other analogous substances, appli-cable also to machinery employed for other purposes. 55 C. Kendall, Mile End, Middlesex. Improvements in apparatus and appliances for working railway brakes, and for effecting communications between the guard, driver, and passengers.

and passengers.

Dated January 8, 1868.

56 J. Mangnall, Glasgow. Improvements in apparatus for preparing coffee and other infusions.

57 W. Tatham, Vulcan Iron Works, Rochdale. Improvements in machines for preparing to be spun cotton, wool and other fibrous substances, and for the production of a web to be converted into felt and wadding, and for display appropriate.

and other fibrous substances, and for the production of a web to be converted into felt and wadding, and for similar purposes.

58 T. P. Lucas, Belmont, Bromley, Kent, and G. H. J. Holt, Sydenham, Kent. An improved method of exhibiting cartes de visite or other portraits or pictures.

59 J. Daglish, Dene House, Seaham Harbour, Durham. Improved apparatus for lubricating the axles of coal tube and other waggons running on rails or tramways.

60 R. Wigram, Leeds. Improvements in horse ploughs.

61 A. B. Brown, Cannon-street, City. Improvements in machinery for raising and conveying weights and conveying power, and in pumping engines suitable for actuating such machinery.

62 W. T. Waite, Salisbury-square, City. Improvements in the treatment of saccharine matters.

63 T. B. Sydserff, Ruchlaw, Haddingtonshire. A ballotvoiting apparatus.

64 J. Rodgers, Hereford-street, Sheffield. A saw-hardening furnace, steam holers and brewing pane, to consume its own snuke and sive fuel.

65 M. Wilkin, St. James-terrace, Paddington, Middlesex, un J. Chark, Cnipp nh un-terrace, Paddington, Middlesex, timprovements in railway brakes.

66 J. Henderson, Auchencairn, near Castle Douglas, North Britain. Improvements in the manufacture of iron and steel, and in furnaces to be used in such manufacture.

Dated January 9, 1868.

Dated January 9, 1868.

67 W. E. Gedge, Wellington-street, Strand. Improvements in the manufacture and in the closing of boxes for

ments in the manufacture and in the closing of boxes for preserving provisions. (A communication).

68 R. Legg, Owen's-row, Clerkenwell, Middlesex. Improvements in the application of steam as a motive power. 69 F. S. Thomas, City-road, Middlesex, Inventions of and improvements in the construction of railway passenger carriages, the carriages of railway locomotives, railway axies, railway buffers, railway girdles, and other matters connected with railway trains.

trains.

70 M. Saunders, Prince's End, Tipton, Staffordshire, and
H. Forrest, Oldbury, Worcestershire. Improvements in
refrigerators.

71 E. Gray, Sheffield. Improvements in the manufacture of plough coulters and other like articles.

72 T. Moore, Bridge-street, Southwark. Improvements
in rotary engines which may be used as pumps or water
meters.

72 T. Moore, Bridge-street, Southwark. Improvements in rotary engines which may be used as pumps or water meters.

Dated January 11, 1868.

73 A. Baumann, Cecil-street, Sirand. Improvements in the construction of hydraulic travelling cranes.

74 J. Holding, Manchester. Improvements in \*emples employed on looms for weaving.

75 F. N. Gisborne, West Strand. Middlosex, and H. Aliman, Amphilli-quare, Middlesex. Certain improved apparatus to be employed for signals on railway trains and for the like purposes.

76 J. Knowles, Droylsden, Lancashire. Improvements in the method of weaving terry, looped, or piled country panes, toilet covers, and other similar fabrics.

77 J. and J. Jordan, Liverpool. Improved means for propelling vessels.

78 T. A. Warrington, Carlton-road, Kentish Town, St. Pancras, Middlesex. Improvements in clips for the attachment of window blinds to their rollers.

79 J. B. Palmer, Handsworth, Staffordshire. Certain improvements relating to the sight protectors, burrel protectors, and muzzle stoppers of firearms.

80 J. Petrie, jun, Rochdale, Lancashire. Improvements in machinery or apparatus for washing wool and other fibrous materials.

81 W. H. Penning, Bishop's Stortford, Hertfordshire. A new system of signalling by compressed air.

82 C. W. Spong, Cliffton-road, Clapton Park, Middlesex. Improvements in the construction and operation of certain parts of railway and other carriages.

83 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of boxes and other hollow articles from paper pulp, and in the unachinery or apparatus employed therein. (A communication).

84 F. C. Matthews, Great Driffield, Yorkshire. Improvements in treating Indian corn to obtain a new product therefrom applicable for use in brewing and distilling, au is as a food for cattle.

85 C. Newsone, Coventry, Warwickshire. Improvements in milk cans.

85 C. Newsone, Coventry, Warwickshire. Improve-ments in milk cans.

NOTICES OF INTENTION TO PROCEED WITH PATENTS. From the "London Gazette," January 12, 1869. 2834 J. Jeavons and C. Martin. Manufacture of iron for plating vessels.
2680 J. M. Hunter. Apparatus for effecting aerial pro-

plating vessure.

2680 J. M. Hunter. Apparatus.

2685 S. Newton. Swing door hinge.

2685 S. Newton. Swing door hinge.

2693 W. E. Gedge. Apparatus for warding off leaves and other matters likely to clog the working of turbines.

(A communication).

2696 J. C. Martin. Manufacture of gelatine.

2702 T. G. F. Dolby. Construction of valves.

2704 W. R. Lake. Looms for weaving. (A communication).

## THE CUTTING TAP.

(ROOKER'S PATENT.)

dvantages of this tap are that no mallet is required to drive it to cask, there is no liquid lost in inserting it, no paper is needed wrapped round the stem, the finest wines or ales are not in the

least disturbed.

In tapping, place the end of the stem against the middle of the bung; press firmly, turning the tap round at the same time. It will cut its way easily through the cork; the piece of cork cut out will afterwards be found in the end of the stem (a b), and can be taken out with a corkscrew.

SYPHON TAPS, requiring no Vent Peg, are made with the Patent Stem.

To be had of all Ironmongers, or Wholesale of

THE

### MECHANICS' MAGAZINE.

LONDON: FRIDAY, JANUARY 22, 1869.

#### PROFESSOR TYNDALL ON CHEMICAL RAYS.

AST Friday evening, at the Royal Institu-tion, Dr. John Tyndall, F.R.S., delivered a lecture upon "Chemical Rays and Molecules," in the presence of an excessively large audience. He said that two or three months ago, while trying some experiments with a compound vapour enclosed in a glass tube, he had occasion to observe the effects of the passage of a powerful beam of light through the vapour. A slight cloud then appeared, which gave him some trouble, because it made him think it possible that in some previous experiments with radiant heat he had been led to ascribe to true vapour absorptive phenomena which in reality were caused by the cloudiness. A little further examination proved that the beam of light itself caused the formation of the cloud. The fact was that the nitrite of amylvapour in the tube was decomposed by the action of the luminous beam into small liquid spherules. He then repeated the experiment by first passing some of the air of the theatre through cotton wool, in order to filter out the dirt. Next, it was sent through a U-tube filled with powdered marble and caustic potash, to absorb the carbonic acid. Lastly it was dried by means of another U-tube Lastly, containing powdered glass and sulphuric acid. The air thus purified was then allowed to bubble through a little nitrite of amyl contained in a little Woulfe's bottle made of a test tube. Afterwards, the pure air charged with vapour was admitted into the great experimental tube, which was 5ft. 6in. in length, and had been previously exhausted of air through one of its stopcocks. This tube was fitted with transparent ends composed of flat discs of glass. When a brilliant conical flat discs of glass. beam from the lamp was sent along the axis of the tdbe, a bright cloud quickly formed at the end nearest the light. Professor Tyndall said that the energy of the waves was absorbed by the first length of vapour they encountered; consequently, they had no power left to set up decomposition at the further end of the tube. He then reversed the position of the tube by putting the transparent end nearest to the light, when a cloud was formed there also. Next, he charged the tube with nitrite of butyl mixed with hydrochloric acid, and upon sending the beam through it, as in the previous experiments, a fine blue colour appeared in the tube, equal to that of the finest sky of Italy. Gradually, the blue gave place to luminous cloud, which became more and more brilliant, and diffused a certain amount of white light through the whole of the theatre.

Professor Tyndall explained that when the particles of the vapour are excessively small, they probably can stop no light; but as they grow larger, they are able to stop the little waves before they stop the big ones. Now, as the blue are the shortest of the visible rays of the spectrum, these appear, therefore, to be reflected before any of the others, and afterwards the luminous rays are intercepted. The causes of the blue colour of the sky, and of its polarization, have always been standing riddles to meteorologists, but he thought that if the same conditions exist in the atmosphere as in his experimental tube, both phenomena were explained. The light emitted from the blue cloud was polarized, as

The lecturer then sent a parallel beam from the lamp, first through a large Nicol's prism, and then along the axis of the experimental tube, with its blue cloud. The cloud then emitted light horizontally, but not in a vertical or downward direction. In fact, it proved to be, virtually, a second Nicol's prism.

The lecturer said that the formation of excessively fine particles in the atmosphere would be sufficient to account both for the light of the sky and its polarization. But the subject is still beset with many difficulties, especially that of the polarizing angle.

#### MANUFACTURE OF CAPS AND CARTRIDGES.

No. I.

THE power that a percussion cap possesses of communicating explosion to a charge of gunpowder, is undoubtedly due to the presence of a certain proportion of detonating or fulminating ingredient. In spite of their great and obviously dangerous character, the preparation of fulminates has always had considerable attraction for chemists and experimentalists, and since the invention of the modern description of firearms, in which the old flint and steel have been abandoned, fulminating powder has been manufactured upon a very extensive scale. In the present and succeeding articles, we shall proceed to give some description of the various processes necessary to prepare that material, and also of the operations attendant upon the manufacture of percussion caps and cartridges, as carried on in the important establishments of M. Gevelot. One of these is situated in the Rue Notre-Dame-des-Victoires, not far from the Bourse, in Paris; a second in the Rue Amelot; and the third at Moulineaux, upon the left bank of the river Seine. The first of these may be regarded as the principal office or head quarters; that in the Rue Amelot is occupied by 400 women, who are charged with the preparation exclusively of the envelopes for war cartridges. It is in the last mentioned premises, situated at Moulineaux, near the bridge of Billancourt, where those operations involving danger to the inmates are carried on. Here the fulminating powder is prepared, the caps and cartridges for sporting purposes manufactured, and those for war filled and completed ready for their mission of destruction and death. Over 1,500 persons, including women and children, are employed at the establishment at Moulineaux, which is divided into two principal parts. One of divided into two principal parts. these is appropriated to the reception of the necessary machinery, and the other to the smaller apparatus and utensils employed in the manufacture.

It is not an easy task to trace the origin and gradual development of the whole tribe of fulminates. Probably, they were, in the first instance, the production of some chance experiment, having a totally different object in view. There is no question but that some of the old alchemists, in their indefatigable and unavailing searches in quest of the philosopher's stone, or the elixir vitæ, stumbled upon numerous detonating compounds. As these, however, possessed no interest for them, apart from their all-absorbing studies, they were in all probability disregarded, and, in many instances, care taken that they should not turn up again in future experiments. About 200 years ago, a chemist of the name of Bailden, gave a recipe for the composition of a fulminating powder, and there is a record in L'Academie Royale of the result of the labours of Lemery in the same direction, particularly with reference to fulminating gold. From the "Collection of Breslau," we find the first notice of the effect of this explosive substance. It is there mentioned that its

simultaneous end of both the mortar and the chemist. Full details of the method of pre-paring fulminate of gold are given in the chemical dictionary of Macquer, where are recorded the experiments of Etmuler, Hoffmann, Bergmann, and Beaumé. The metal should be first dissolved in aqua regia, composed of spirit of nitre and salammoniac, and then precipitated by the addition of a proper quantity of any fixed alkali. The precipitate is of a yellow colour inclined to red, and, when washed and dried, constitutes fulminating gold. The other precious metal is also endowed with the faculty of assuming similarly dangerous and destructive properties as its more noble fellow. Fulminating silver has been long known, and equally dreaded by those concerned in its preparation. The celebrated chemist, Berthollet, towards the end of the last century, investigated this perilous compound with considerable ability and pertinacity, and procured it by the following formula. Dissolve fine silver in nitric acid; precipitate the solution by adding lime water; decant, and expose to the air for three days. After that period, treat the pre-cipitate with fumes of sal ammoniac, when it will assume the form of a black powder. This dried by exposure to the air is fulminating silver. It is said that another of these extraordinary compounds, namely, the fulminate of mercury, was discovered in 1775, by Bayen, but there are no written records left of the discovery. Macquer, indeed, gave the name of fulminating powder to a mixture, composed of three parts of nitre, two of alkali, two of tartar, and one of sulphur. But that this was not a true fulminate is easily demonstrated by the circumstance that it required an elevation of temperature to cause it to explode, whereas the genuine article demands nothing beyond a smart blow, and sometimes not even that. Towards the close of the last century, Fourcray, Vanquelin, and the well-known Berthollet especially, turned their attention to applying these fulminating preparations to effecting the discharge of firearms. Chlorate of potash was also experimented upon with the same intention, but the blowing up of the powder mills at Essonne, in which Berthollet carried on his experiments, acted rather as a damper upon the zeal of those who advocated its employment.

It was reserved for Howart, in the year 1800, to determine accurately the composition and physical properties of fulminate of mercury, which, for some time subsequently, was known as Howart's quicksilver. About this time, a Scotch gunsmith took out a patent for a gun, in which the flint was replaced by a hammer, which acted upon a fulminating substance, and so communicated the explosion to the charge. Some of these arms were imported into France. Ten years afterwards, a M. Pauly patented the first French percussion gun. It was double-barrelled, breechloading, and the cartridge carried its own priming of fulminate. Upon pressing the trigger, a small iron rod was set in motion, which struck the priming, and exploded the cartridge. In addition to many imperfec-tions, the force of the explosion of the priming often caused both barrels to be discharged simultaneously, to the great annoyance and inconvenience of the soldier or sportsman. After the year 1808, more than a couple of hundred patents for percussion guns were taken out and handed over to gunsmiths, who were particularly careful to conceal the nature and composition of their respective fulminates. The first priming pieces were in the shape of little bullets covered with wax and varnish, which were placed in a small hollow or pan, and struck with a percussor or hammer. effect of the explosion was to produce a considerable dispersion of the wax and varnish, emitted from the blue cloud was polarized, as could be proved by examining it with a crystal of tourmaline. Nay, more; it could be made to act in a very peculiar manner as a Nicol's The mixture exploded, and there was a fulminate, but they were found to be too

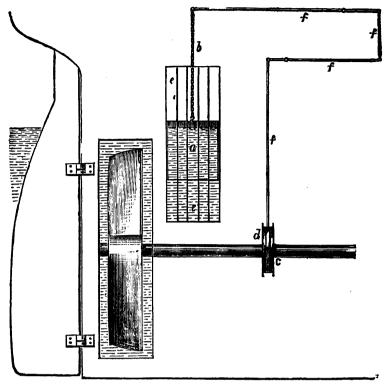

fragile, and also difficult of manipulation. All these attempts proved failures, and were supplanted by the invention of the percussion cap by Egg. It was imported into France by a gunsmith named Deboubert. A French gunsmith, Prélat, claims to have invented the percussion cap anterior to Egg. He patented and applied them in 1819 to what he was pleased to call his thunder gun. It was not until after the experiments of Charoy and Bruneel, towards the year 1840, that the French army definitely adopted the large copper cap, slightly conical, with a flat rim, in which the fulminating powder was secured by a varnish of gum-lac. The invention, however, was adopted nearly twenty years previously for guns intended for sporting purposes, the new ones being made upon that system, and the old ones converted to it. The clder M. Gevelot was the principal promoter in France of this new branch of industrial manufacture, and, in 1820, he added it to the manufacture he already carried on of arms and military equipments.

To be the first to carry on the preparation of a material so dangerous in its nature as to imperil the safety of those who are concerned in it, requires a large share of courage and resolution. It might justly have been argued that, if these detonating substances had been found so exceedingly unsafe as to cause the death of those who merely experimented upon them, and who were likely to be protected by every means that their science and experience could suggest, what would be the results when they came to be handled by careless and inexperienced workmen? No doubt accidents have arisen, but it will be seen, in the course of our narrative, that where proper and stringent precautions are taken, they are not more frequent than those that happen under circumstances infinitely more favourable, and, in fact, do not surpass the number that may be reasonably anticipated in a world of chance. M. Barruel, assistant to M. Thénard at the Faculté des Sciences, in the year 1800, lost his right arm by an explosion of fulminate. Some years afterwards, M. Bellot, a distinguished scholar of l'Ecole Polytechnique, suffered a similar mutilation, and an artisan was killed upon the spot by the explosion of the damp salt which he had slightly touched with an iron point. Un-daunted by the disastrous precedent that cast an ominous shadow over his intended manu-facture, M. Gevelot started the work upon his own premises, and the contents of our succeeding articles will be the best proof of the well merited success that rewarded his courage and perseverance.

## REGULATING THE VELOCITY OF THE SCREW PROPELLER.

In a gale of wind, the stern of a ship is lifted high out of the water, and along with it the screw propeller, many times every minute. It is at these moments the great danger exists of breaking the blade of the propeller, or of twisting off the main shaft, as has been the case with many screw ships of late. The public at large have very little knowledge of the great marginal velocity of the screw which is necessary to propel the ship at ten or twelve knots an hour; 45 or 50 miles an hour is the ordinary screw speed, but when the stern is lifted out of the water, and the resistance removed from the blades, the screw revolves at a speed equal to one or two hundred miles an hour. True, this is but for a moment, yet it has proved to be long enough to send some of our best ships to the bottom, and this unsatisfactory condition of matters arises from the absence of any efficient means of checking the increased velocity of the screw as it rises out of the water in rough weather. To meet the requirements of the case, Messrs. F. and C. Hancock, of Dudley, have invented the apparent

### HANCOCK'S SCREW PROPELLER REGULATOR.

ratus for regulating the velocity of the screw shown in the annexed engraving. Messrs. Hancock will be well remembered by our readers as the inventors of a screw propeller, which was described in our issue for September 18 last year, and which upon trial gave some remarkably favourable results.

In the present instance, in order to maintain the screw as near as possible at an uniform velocity in all weathers, Messrs. Hancock fix to one or both sides of the stern of a screw vessel the flat floating buoy a, which is wedge-shaped in plan, the thin edge being towards the bow of the vessel and close to the side. This buoy is held in position by strong V-shaped bars of iron e; one portion of these bars is attached to the ship, and another portion projects from the side just far enough to receive the buoy. The buoy is braced with iron to work into the V-shaped bars, and in this position the buoy is allowed to rise and fall freely, but is held firmly from any side action, easily moving up and down along the back and front V slides. The buoy is made of such a specific gravity as that it only just floats. This is the arrangement which is used on vessels already built, but in new ships a recess will be formed in the stern, which will enable the buoy to rise and fall flush with the run aft. To the buoy is attached a chain b, and on the main shaft is fitted a drum d. On this drum is a brake strap, and in connection with the brake is a compound lever ff, which is connected at the other end with the chain which is attached to the buoy. By this means, the velocity of the screw is regulated, and kept from any injurious speeds.

and the resistance removed from the blades, the screw revolves at a speed equal to one or two hundred miles an hour. True, this is but for a moment, yet it has proved to be long enough to send some of our best ships to the bottom, and this unsatisfactory condition of matters arises from the absence of any efficient means of checking the increased velocity of the screw as it rises out of the water in rough weather. To meet the requirements of the case, Messrs. F. and C. Hancock, of Dudley, have invented the appa-

largest and smallest screws can, therefore, be checked and regulated by this self-acting buoy, which does not require anyone to control it. Every time the screw rises out of the water, the buoy sinks down in its slides, and brings its own weight to bear, through the compound levers, on the brake strap; thus, in a moment, regulating the velocity of the screw. One important feature in this invention is that it acts momentarily, which is so essential to the safety of the ship; and the screw, being immediately disengaged from the brake, has the full power of the engine upon it at the time it is most required to propel the ship forward out of the trough of the sea. This cannot be the case when we rely upon the cutting off the steam in checking the sudden increased velocity of the screw, inasmuch as the steam is often cut off, leaving one cylinder full, which exerts its whole power on the screw at the time the screw is high out of the water. Consequently, the screw is whirled round at a frightful velocity, making everything tremble and vibrate throughout the ship.

All the dangers that attend a screw ship in a gale of wind, beyond those incidental to a sailing vessel, are therefore done away with by this simple arrangement of the floating buoy. There are other advantages arising out of this invention beyond the increased safety afforded by it to the ship. There is, for instance, a great saving of fuel, for every time the screw gets an increased velocity from being lifted out of the water, there is a great waste of steam, and consequently of coal, and very little propulsion on the ship. This is one great reason why a screw ship labours so much in a strong gale of wind, and makes so little progress. The steam is often out of the cylinders when the screw is deeply immersed, owing to the inefficient system of cutting off the steam, which often leaves the ship a rolling log in the trough of the sea. This would, of course, be obviated with the brake action afforded by Messrs. Hancock's apparatus, which, from its practical merits, will doubtless come into use in all sea-going vessel driven by the screw propeller.

#### KING'S COLLEGE.

N the evening of yesterday week, the halls, class rooms, and other apartments of King's College presented an unwonted appearance of gaiety and animation, which contrasted in a marked manner with their usual staid and grave appearance. The sombre academical garb gave place to all the variegated hues of ladies' dresses, and the voices of the lecturers were superseded by sounds of music and song. The occasion was a soirée upon a scale of considerable magnitude, which was given by the principal —the Rev. Dr. Barry—and academical staff of the College. Such an event had not taken place for about ten years previously, and its success was complete. In the great hall and the two adjoining drawing rooms were placed numerous works of art, the walls being hung with valuable paintings by Millais, Frith, Cattermole, O'Neil, Stanfield, Rosa Bonheur, Ward, Hook, and other eminent artists. Her Majesty lent an interesting collection of weapons, including the sword of Charles I., left at the house in which he passed the night previous to the battle of Naseby. Near it was a sword which once belonged to Hampden, and which is said to have been wrought by Cellini. A number of specimens of silver electro-plate, glass, and china ware were lent by leading manufacturers in those several branches of art. In another apartment, photographic illustrations were given by the the oxy-hydrogen microscope, by Mr. Close by, Gassiot's vacuum G. Dawson. tubes were exhibited, and a large induction

coil was at work.
Sir Charles Wheatstone kindly exhibited various magnetic and electric apparatus, his brilliant coronet of vacuum tubes attracting especial attention. In another room close by, we found some exceedingly interesting experiments in the way of cohesion figures, which were produced by dropping various oils upon the surface of water. The lime light, a magnifier, and a reflector, threw these figures on to a screen, where their vagaries produced considerable amusement, although the smell of some of the oils did not invite a protracted visit from the ladies. The Microscopical Society sent a number of microscopes well supplied with interesting subjects. In another apartment, the vibrations of air in organ pipes were presented to the eye by means of gas flames reflected in a revolving mirror; the flames themselves were also shown to be musical. The novelty of the evening, however, was the zirconium light of M. Caron, which was then introduced for the first time into England. The light is somewhat similar to the lime light, but exhibits a more intense brilliancy. The band of the Grenadier Guards enlivened the evening with the performance of an excellent selection of instrumental music, whilst at intervals the vocal music of the Civil Service Musical Society was listened to with pleasure in the great hall. The soirce was most successful, and reflected great credit upon the committee of management, which consisted of the following gentlemen:—The Rev. Dr. Barry, principal; the Rev. G. F. Maclear, head master of the school; Professor Adams, Professor Bentley, Professor Cutter, Professor Cutte Delamotte, Professor Grey, Professor Miller, Professor Mariette, and Mr. J. W. Cunningham, secretary. The doors were thrown open at eight o'clock, and from that hour until nearly twelve, a ceaseless stream of visitors continued to circulate through the various apartments. We believe there were various apartments. three and four thousand persons between present during the evening.

#### METROPOLITAN IMPROVEMENTS.

IF anyone is desirous of knowing what is I going on in and around this busy metropolis in the way of improvement without the majesty on May 13 last.

The new streets next come in for notice.

him to read the annual report of the Metropolitan Board of Works. Here he will find the whole metropolis laid open before him with reference to what is being done to improve its drainage, to purify its river, to utilize its sewage, to improve its streets, so as to facilitate the swelling traffic of an over-grown city, to reduce its bills of mortality, and, in short, to render it clean, sweet, healthy, and accessible. The annual report for 1867-8, which has recently reached us, is full of interest, and treats, as usual, upon a great variety of subjects. We first find the great variety of subjects. We first find the Board dealing with the main drainage of the metropolis, and here we are informed-which, by the way, we already knew-that with the exception of portions of the northern low level sewer and the pumping station at Abbey Mills, the whole of the works comprehended in the main drainage scheme have been completed and in full operation for the past three years. The area drained by the Board's main and branch sewers is about 117 square miles, and the length of sewers constructed is about 82 miles. The natural effect of the main drainage works has been to secure in a still higher degree than heretofore the purity of the Thames within the limits of the metropolis. The marked increase of fish in this portion of the river, and the absence of offensiveness during the summer, which has been remarkable for the long continuance of a very high temperature and the small amount of rainfall, are clear proofs of its improved state, and give a guarantee that there will be no return to those conditions which in the year 1858 gave rise to such well-grounded alarm in relation to the health of London. Several matters of detail still remain to be carried out in connection with the purification of the river, such as preventing the discharge of offensive matters from gas works and manufactories into the river, and these are receiving the attention of the Board. With regard to the utilization of the sewage, the Board have had some operations carried out during the last few years, the results of which have tended to confirm the previouslyexpressed opinion of the Board with regard to the value of sewage as a fertilizer of the soil. A sample of wheat was sent to the Board grown on land which bore a wheat crop last season, and produced by means of unexhausted manure remaining on the land after 4,000 tons of sewage per acre had been applied to it last year, the same land having produced 71 tons of grass per acre last sea-

Turning to the Thames Embankment, both north and south, we have a very lengthy report, the substance of which may be given in a few lines. Generally, we may state that the first portion on the north side, extending from Westminster Bridge to Waterloo Bridge, has been completed and opened, as has also the second portion, from Waterloo Bridge to the eastern end of the Inner Temple Gardens. With regard to the third portion, between the Temple and Blackfriars Bridge, there has been considerable delay in consequence of negotiations with the Metropolitan District Railway Company, but it has not been without corresponding advantages. A recent hindrance—to which the report does not refer, being dated June 30, 1868—was the giving way of the piling, by which the works became flooded. The Board goes on to observe that while, on the one hand, a large saving in the cost of construction will be effected, on the other the continuation of the Embankment in a solid form, with a roadway of 100ft., will give to the work an uniformity from which an open viaduct would have detracted. embankment on the south side of the Thames extends from Westminster Bridge to Gunhouse-alley, Vauxhall, about 4,300ft. About 81 acres of the ground forms the site of the proposed new St. Thomas's Hospital, the

The chief of these is the new street from Blackfriars-bridge to the Mansion House. The street will extend from the termination of the northern embankment at Blackfriarsbridge to the Mansion House, and the total length will be 3,450ft., and its width 70ft. As the line taken by the street passes through some of the old City burial-grounds, it became necessary to make arrangements for the removal and reinterment of the coffins and human remains. A contract has been entered into to remove the remains and re-inter them in the Great Northern Cemetery for the sum of £950. The claims for property required were £2,526,682 19s. 1d., which were settled for £1,938,217 18s. Since the date of the Board's last report, the Middle-row improvement has been completed. The block of buildings forming the north side of Middle-The block of row, and which tended so much to impede the traffic in Holborn, has been removed, and the ground thus cleared thrown into the public way. The new roadway and footway were opened on December 24, 1867. roadway now averages 56ft. in width, with a footway 16ft. wide on the north side, and 20ft. on the south side of the road. The object of the Whitechapel improvement is to form a new street, extending from Backchurch-lane to Leman-street, with a view to affording an improved means of communication between Whitechapel and the Commercial-road. During the past year, the acquisition of the properties required for this improvement has been satisfactorily proceeded with, and the demolition of the buildings is now rapidly going on. The estimated net cost of forming the street is £115,364.

Mindful of the necessity of open air recreation as a means of health, the Board have not neglected the parks which they are carrying out. The demand for building ground near the metropolis, arising from its rapid exten-sion and the removal of dwellings, chiefly those of the poor, which has become necessary to carry out the extensive railway and other public works in progress, gives an importance to the subject of open spaces which has never before attached to it. The Board are fully alive to the necessity, which springs out of rapid extension of the metropolis, of securing absolutely as much open space as shall provide for the inhabitants of London and its suburbs the proper means of health and recreation. Finsbury and Southwark Parks will be completed during the ensuing spring, and will shortly after be available for the use of the public. The area of Finsbury Park is 116 acres, and Southwark 63 acres, at a cost respectively of £56,869 and £55,160.

The arrangements of the Board for the protection of life and property from fire throughout the area under their jurisdiction, are advancing rapidly towards completion. Two years and a-half had clapsed, at the date of the report, since the Metropolitan Fire Brigade Act came into operation, and a comparison of the means now at command for extinguishing fires with those which were in existence when the Board assumed the duty, will suffice to show the progress and extension which have been effected. The number of stations handed over to the Board by the late London Fire Engine establishment was 17, exclusive of two floating engines on the river. There are now 44 stations on land and 3 on the river. The number of men forming the staff of the brigade when it came under the jurisdiction of the Board was 130; the present number is 314. The number of fires attended was 1,492, and 2,090 chimney fires; and as regards the latter, in 1,528 cases, penalties were imposed by magistrates.

Amongst the minor, although equally important, details of the Board's work, we may first refer to the gas supply of the metropolis. This important subject has again, during the past year, been much under the consideration

price not exceeding 3s. 9d. per 1,000 cubic feet for common gas of an illuminating power of not less than sixteen candles, subject to revision every year by the Board of Trade.

Next, we have the question of improvements by local boards. It appears that the Board have, upon the application of several local have, upon the application of several local authorities, during the past year, agreed to contribute to the cost of widening various thoroughfares in the City of London and other parts of the metropolis. The estimated cost of these improvements was £99,797 5s., and the Board agreed to contribute £33,123 2s. 6d. Attention has been given to the storage of petroleum. A bill was intro-duced by Her Majesty's Government during the past session to extend the provisions of the Petroleum Act of 1862, which was passed, and the Board trust that the effect of the measure will be to promote a better observ-ance of the law on the part of the dealers in petroleum and other substances of a similar nature.

The financial transactions of the Board are of course, of considerable magnitude, and in keeping with their other operations. At the date of the last report an amount of £15,843 18s. 5d. remained due to the Board from the Bank of London; this sum has since been paid, together with £1,658 19s. 11d. for interest. During the past year loans have been paid off to the amount of £261,900, but new loans have been entered into amounting to £1,180,000. The total indebtedness of the Board at the present time is £6,903,366 13s. 4d. Since its constitution, the Board has sanctioned the formation of upwards of 1,300 streets, the applications during the past year having been 288, of which 202 were granted, and 86 refused. We have frequently called attention to the re-naming of streets and the renumbering of houses-matters which have proved highly satisfactory to the public. It appears that during the year orders have been transmitted for re-numbering streets, by which means 466 subsidiary names have been abolished, and precision of reference much simplified, to the great convenience of the public. A very large number of streets still needs revision as to their naming and numbering, and as the requisite operations are necessarily slow, and great accuracy is required, it will probably be some time before the current demands are satisfied.

The Metropolitan Board of Works had been constituted twelve years at the date of their report-which, by the way, we should like to see issued earlier than six months after date-and during that time they have expended large sums in carrying out the objects contemplated by the Local Management Act of 1855, and various other statutes passed in subsequent years, under which largely-extended duties have devolved upon them, and these sums have been uniformly raised by local taxation on the occupiers of property within the metropolitan area, the only exceptions being the coal and wine duties, the Government contribution of £10,000 per annum, and the annual amount received from Government contribution of £10,000 fire insurance companies in aid of the Fire Brigade. There is no doubt that in return for this taxation the inhabitants of London and its suburbs have received great benefits from the works of the Board, among which, as the most prominent, may be mentioned the system of main drainage, the embankment of the river, the formation of new thoroughfares, the establishment of parks, and the preservation of open spaces; beyond these, there are many minor improvements which the Board have from time to time aided the local authorities in carrying out by granting pecuniary contributions. But, notwithstanding that much has been done during the past few years for improving the condition of the metropolis, it is clear that its growing requirements will be very far from met unless additional facilities for traffic are provided, commons and open spaces secured, and other works executed which will necessarily involve

a large expenditure. The Board express a hope that the attention of the Legislature will shortly be directed to the important question of readjusting the taxation between the owners and occupiers of property in the metropolis, and that ultimately the requisite revenue will be placed at the disposal of the Board, without the necessity of imposing additional burdens on those who are already so heavily taxed—a "consummation devoutly to be desired" by that victim of circumstances, the British taxpayer.

OTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

HYDROGEN A METAL-GREEN PIGMENTS BATTERY-THE AMALGAMATION OF IRON.

HEMISTS have long argued, from certain analogies and behaviour, that the element hydrogen must be a metal, just as we infer, from the manners of a man, whatever his dress, that he is a gentleman or the reverse. By itself we only know hydrogen as an invisible gas. It was one of those which defied all the efforts of Faraday to press and freeze it into the solid or liquid form. But what Faraday was unable to do to hydrogen the gas readily does for itself-that is, takes the solid form. Mr. Graham has shown that hydrogen readily enters into, and, as he supposes, combines with the metal palladium, forming a true alloy of the two metals. He has determined the proportion of the two, and the density of the alloy, and thus is able to determine that the density of hydrogen=2 He has also measured the increase of bulk acquired by the palladium in its union with hydrogen, estimated the electric conductivity of the alloy, and found that it follows the law observed in all true alloys, and thus Mr. Graham asserts the real metallic nature of the invisible gas hydrogen. We shall refer to this matter again shortly, when further facts are before us.

The continued agitation some time ago about the danger of arsenical greens set chemists actively to work to produce pigments of the same colour free from poisonous qualities. We have already recorded the discovery of several processes for making harmless mineral greens, and to-day we find another, about which, however, not having had the opportunity of making an experiment, we can express no opinion. The inventor, M. Moulin, makes, first of all, a solution of zinc in hydrochloric acid, and a solution of oxide of cobalt in the same acid. The proportions are varied according to the shade of colour required; but taking always 100 parts of zinc there may be from 1 to 15 of oxide of cobalt. These two solutions are poured together and mixed while hot. Then a solution of carbonate of soda is added by which a precipitate of the mixed hydrated carbonates of zinc and cobalt is produced. The precipitate is washed with a large quantity of water to remove chloride of sodium, and then it is dried on chalk or plaster of Paris plates, and subsequently heated to 100deg. Wedgewhereupon it becomes of a yellow colour which changes to green as the mass cools. inventor states that if some sulphate of alumina be substituted for some of the zinc, the colour will have a bluish shade according to the proportion of alumina employed, about which there can be no doubt, as the compound formed will more or less resemble cobalt ultramarine. The great difficulty in the production of these colours will be the management of the heat. The inventor speaks of 100deg. Wedgewood. This temperature may mean anything between 1,000deg, and 1,500deg. Centigrade, or from a dull to an intense red heat.

A galvanic battery, which will be found very

enient under some circumstances, is described by M. J. Ney. A plate of amalgamated zinc is immersed in solution of chloride of ammonium, or,

some resemblance to Jacobi's chamber battery and like that is available where acid batteries are objectionable. The action consists in the decomposition of the sal-ammoniac, the chlorine of which goes to the zinc, while the ammonia passes to the carbonate of copper. When exhausted, the action carbonate of copper. is revived by the addition of sal-ammoniac.

Writing of batteries, reminds us that amalgamated iron plates have been recommended for use in place of amalgamated zino, the iron being much cheaper, and electrically of very nearly the same value as the zinc. But to amalgamate the iron has been a difficulty. Several methods have been suggested, more or less troublesome and expensive; but the following is comparatively simple, and is said to answer extremely well. The iron, carefully cleaned, is first done over with a solution of chloride of copper in hydrochloric acid, and thus a thin coating of metallic copper is obtained on the Upon this a solution of bichloride of mercury in hydrochloric acid is applied, and the whole surface becomes amalgamated. Whether whole surface becomes amalgamated. Whether the mercury really combines with anything more than the superficial coating of copper is more than we can say at present. But we are told that the coating completely protects the iron from rust. Various applications of this discovery suggest themselves—one mentioned by the author is, as we have said, the use of amalgamated iron plates in batteries.

#### ST. THOMAS'S HOSPITAL.

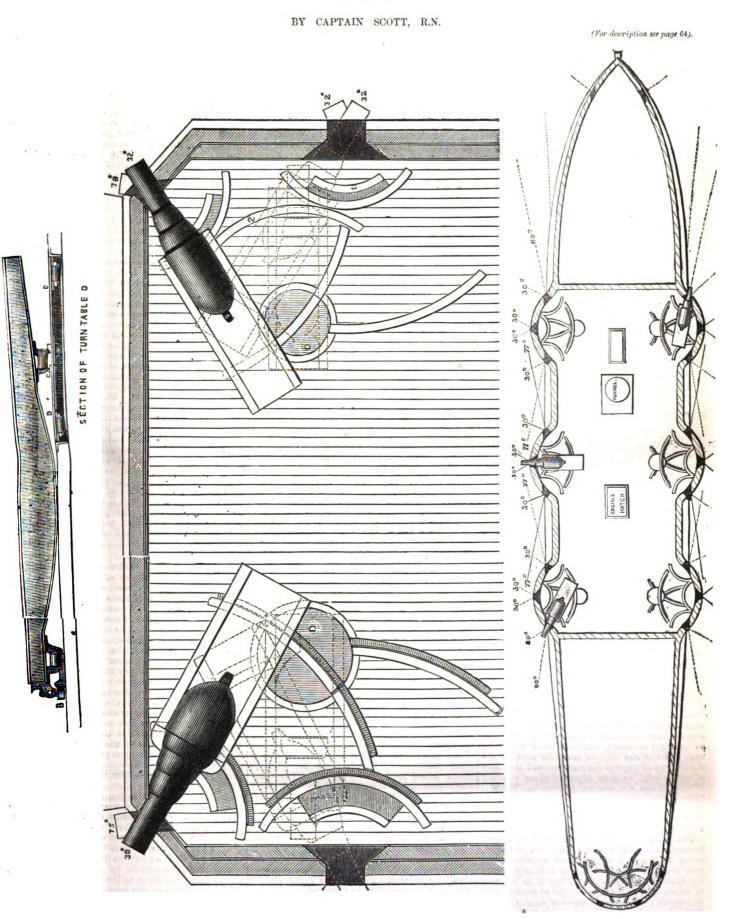

WE are glad to report that the construction of the new St. Thomas's Hospital is progressing very satisfactority. The works are let under two contracts. No. 1, the basement story, was taken by Mr. William Webster, the contractor for the Embankment, who has now brought his work to a finish, with the exception of a small portion of the nnish, with the exception of a small potential of any concrete arching under block No. 9, and the foundations of the boundary wall towards Palace New-road, which latter the architect does not wish executed at present. Contract No. 2, the contractor for which is Mr. John Perry, is progressing rapidly, there being not less than 700 men, artificers, and labourers employed daily on the works. The external masonry and internal walls of block No. 1 are carried up to an average height of 6ft. above the level of the one pair story. Of blocks 2 and 3 the walls of the eastern portion average 11ft. above the one pair story, and the walls of the pavilions 8ft. 3in. above. In block No. 4, the walls of the eastern portion are 11ft. above the one pair story, and the walls of the pavilion 8ft. 3in. above the same level. In block No. 4, the walls of the eastern portion are 11ft. above the one pair story, and the pavilion walls are 4ft. above one pair floor. The walls are 11ft. above the one pair story, and a portion of the above the one pair story, and a portion of the internal masonry of the chapel is carried up to the same height. The brickwork and masonry of block No. 6 is about 11ft. above the one pair story, and the pavilion walls are at an average of 4ft. above the one pair level. The walls of block No. 7, at the eastern side, are 10ft. above the one pair level, and the pavilion walls are built up to level of 6ft. above floor. The walls of the eastern portion of block 8, average 2ft. below the one pair level, and the pavilion walls, as in the preceding case, are carried up to level of one pair floor. Block No. 9 was not commenced until the end of September, and the walls are now 6tt. above the ground floor level. The entire of the wrought-iron girders for the first floor are fixed throughout, except to block 9, and these are on the ground ready for fitting, as well as the greater portion of the ironwork for the second floor.

THE MANUFACTURE OF WATCHES AND CLOCKS.

—A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons by M. J. Ney. A plate of amalgamated zinc is immorsed in solution of chloride of ammonium, or, if the battery is to be carried about, may be set in sand wetted with a solution of the chloride. The copper plate is set in a porous vessel, filled up with carbonate of copper—the common mineral carbonate will answer the purpose, it is said. This combination, which is certainly cheap, gives, we are told, a lasting and strong current. It bears it to the notice of the intending purchaser.—| ADVY. |

# THE TURNTABLE SYSTEM OF WORKING BROADSIDE GUNS.

#### SOCIETY OF ENGINEERS.

T the first ordinary meeting of this Society for 1869, held on Monday evening last, Mr. Charles A 1869, held on Monday evening last, Mr. Charles
Julian Light, vice-president, in the chair, the
names of the council and officers for 1869 were
announced, viz., Messrs. F. W. Bryant, president;
W. Adams, C. J. Light, W. Naylor, vice-presidents;
J. H. Adams, B. Fothergill, R. Harris, J. Hendry,
E. J. Leonard, W. Macgeorge, G. W. Stevenson,
G. Waller, A. Williams, honorary secretary; Porry
F. Nursoy, auditor; and George W. Harris, secretary. The Society's accounts for 1869 were read,
and the following names of candidates for election and the following names of candidates for election were announced:—Messrs. Alfred Rubery and Charles C. Gibbons, as associates. Premiums for 1868 were presented to Dr. Edward Cullen for his papers on the surveys of proposed lines between the Atlantic and Pacific Oceans, the Panama Railroad, and the Darien Ship Canal; to Mr. Sydney A. Reade, for his paper on the sewerage works at Redhill; and to Mr. Arthur Rigg for his paper on the screw propeller. Mr. F. W. Bryant, president for 1869, was then introduced to the meeting, and delivered his inaugural address. At the close of the meeting, the following candidates for election as members were balloted for and duly elected:— Messrs. Thomas Carpenter, Ballarat, Colony of Victoria, Australia; and Robert John Mostyn, 18, Great George-street, Westminster.

#### THE PRESIDENT'S INAUGURAL ADDRESS.

In taking my place for the first time as president of this Society, I thank you for the honour you have conferred on me in electing me your president, an honour which I greatly esteem, and hope, with the assistance of the council, and the cooperation of the members generally, that I shall be enabled to carry out my duty to the satisfaction of all, and the advancement of the Society It is now more than ten years since I joined this Society, and I have much to thank it for in enabling me to glean a great amount of information in the various branches of the engineering profession. which I could not have obtained by my own practice alone. Therefore, I consider a society like this is of great value to a young engineer, and in many cases to those who are seniors in the profession. If a member attends regularly at our meetings, as he ought if he possibly can, I do not believe there is any paper read, or lecture given, from which he may not obtain some advantage. either from the paper itself, or by its causing him to think on the subject on which the paper is written. Then there are our visits of inspection to the important works in and around London, which, I trust, may be extended to more distant localities Those visits, excellent in as occasion affords. purpose and effect, are most valuable to all the members who attend on those occasions; for it is not only from one's own observations, but from the remarks of, and discussions with, those present at the time on the works actually in progress, that he who seeks to learn has every oppor-tunity of so doing. One of our older institutions, which holds periodical meetings at the larger manufacturing towns, is an instance of the advantage of these visits, as there is no doubt that the large increase of its members is mainly owing to this arrangement. I have much pleasure in remarking the kindness and courtesy with which this Society has always been received at the various works it has visited from time to time. I am happy to say I can congratulate you on the general advancement of the Society, both in numbers and position. When I first joined the Society we numbered but 127, and now that number of its When I first joined the Society members and associates is quadrupled. We have, as honorary members, many of those who take rank amongst the highest scientific men in the world; and as regards the members and associates of our Society, we have representatives of every branch of the engineering profession. There is scarcely any part of the world, where engineering works are being carried out, that there are not some of them to be found, working either as principals or assistants.

True it is, that since the last financial panic there has been considerable depression in our profession, owing to the want of confidence engendered by over speculation; but that can certainly not be the fault of engineers. Doubtless it is the duty of an engineer to carry out works as economically as possible; but there is another duty which he should be most careful of, and that is note to underestimate the value of any work, as that will in-evitably lead to confusion. Difficulties occur both at home and abroad, which one could

sometimes it seems as if he were expected to see beyond "mortal ken." I hope and believe that this depression will be gradually removed, and that we shall see engineering improvements increasing here and abroad, to the advancement of our profession and the benefit of mankind. I say to the benefit of mankind; for is it not to the drainage engineer that we owe the health of towns and agricultural improvements? to the railway engineer quick transit, the removal of goods, and the opening up and civilization of whole districts? to dock and harbour engineers the safety of the navies of the world? and so to all the branches of our profession, which tend directly or indirectly to the good of mankind in general.

And although there has been this depression, and men say, "there is nothing more to be done in England," surely this must be wrong. Are all our towns properly drained? all our rivers bridged over? all the docks, harbours, piers, and lighthouses, defence of shores (much wanted in many places), all water supplies and irrigations completed? all connecting lines of railways made? Are even the existing main lines perfect? as recent accidents lead us to think that it will be necessary to have separate lines for passenger and goods traffic-in fact, some of the engineers are taking steps to secure the necessary ground. Is the utilization of sewage properly done? Surely, then, with the return of public confidence in properly matured schemes, we may hope that engineers of Great Britain may find that there is vet something to be done in their native country. In and around London of late years there have been many great and remarkable works executed, some not vet completed, and I can scarcely imagine a better school for engineers, if they have properly studied the different important engineering operations that have been carried out. Many of these works will mark the present era of engineering for generations to come. Take, for instance, that grand work the Thames Embankment; although not yet completed, the portion now opened shows the great improvement it will be to London. I hope to see it extended on both sides of the river, so that the improvement may be made complete in the metropolitan district. The main drainage works are in full progress, and in a comparatively short time we shall doubtless have Lon don perfectly drained, and, as a natural result of this, the health of the inhabitants improved. The river Thames has decidedly improved in purity during the last few years, as I have had good opportunity of knowing. Various kinds of fish, from the dace to the porpoise, certainly made their appearance during last summer in the neighbourhood of Blackfriars Bridge. Then we have the Metropolitan Outer and Inner Circle Railway although not quite completed, yet the work already done is sufficient to command the admiration of all observers, professional or non-professional. I consider it, as a work, a credit to to our profession. Such a varied practice cannot have occurred in any other railway I know of, and it is, I think, a good example, showing that, whatever difficulties arise in the construction of works. they can be successfully met by a good engineer. Then there is the East London Railway in course of construction, which will no doubt be of great service, when completed, for public traffic; also other small branches, which are of importance to the main lines they belong to, and all tending to complete the railway system.

We have also had new docks-I allude to the Millwall Docks-opened during the last year, and improvements and enlargements at the West India Docks, which will no doubt be appreciated by the mercantile communities of London, and I may say of the world. Good dock accommodation is great desideratum, though sadly neglected in places where it is greatly needed. There are many positions on the coasts of England where good docks would be of great value and convenience, and I hope to live to see many such posi-tions naturally formed for harbours and docks taken advantage of for their construction. The bridge over the Thames at Blackfriars has made good progress during the last year, and I expect to see it open for public traffic about the middle of this year. This will also be a great metropolitan improvement. The Holborn Valley Viaduct will be of great utility, and is also progressing rapidly towards completion. There is an improvement very much wanted in London, and that is a footway bridge crossing over our principal thoroughfares; and in places like Regent Circus, or the bottom of Fleet-street, a four-way bridge

might be erected at a small cost, and would very soon prove if it were of practical uso. Engineering work in Great Britain has generally been very slack during the last year, It has had many things to diminish its chance of prosperity. The Abyssinian war, the unsettled state of and revolution in Spain, and the doubtful position of politics with regard to war in Europe, all tended to the stagnation of work. prosperity of civil engineering peace is absolutely and I hope and think we may look fornecessarv ward to it with confidence.

The general election, without doubt, materially interfered with engineering establishments all over the kingdom. I think, however, I may congratulate you upon the fact, that the prospect of an increase of work is decidedly brightening in the iron districts, which is a good criterion for our profession generally, although report states that Belgium houses have an immense amount of work in hand. The "Iron Trade Review" of December 23, 1868, states that they "have now secured, or are in treaty for, contracts to the extent of something like 90,000 tons of rails"; and further on remarks :- "We may ask, what English firms durst venture to take contracts for such a period in advance in the present state of the market, in consequence of the constant insecurity from a movement on the part of the workmen for advanced wages; and experience has shown that this is almost sure to be their tactics whenever they know that employers have heavy con-tracts on hand." This, I am sorry to say, I believe This, I am sorry to say, I believe to be the case. Every man has a right to obtain as much as he can for his labour; but it is unfair, after a master has taken a contract, for workmen to demand a rise of wages before the completion of that contract, and it is much to be regretted that workmen should do so, as in many cases it prevents the ironmasters of England from taking work. It is a difficult question, but one of great importance, to institute a proper system of arbitration between men and masters; and whoever could arrange a good method of effecting this would be rendering his country a great service. The export trade of manufactured iron into France has decreased by some 5,000 tons in 1868 from that in the preceding year; still I perceive a great probability that the decrease will be altered to an increase during this year. I am glad to find, also, from public reports, that our exports of iron to America are decidedly on the increase; and from the friendly relations now existing between the two countries, and also from the low state of stocks of iron generally, we have every reason to expect that our exports will be much larger during the present year, and I most sincerely trust that not only mutual improvement of commerce, but of good feeling, will continue between Great Britain and America and all other parts of the world.

Certain I am, with regard to our nearest neighbours, that the sentiment of peace which the Emperor has lately expressed, confirms my ide the probable increase of trade generally. While on the subject of iron, I have great pleasure in remarking that we have to welcome a new society lately formed, under the title of the Iron and Steel Institute, and I learned that, in the short space of two months, 150 gentlemen directly connected with the iron and steel interest have signified their intention of joining the new institute. There can be no doubt that much good will result from the information they will be able to afford our profession. In Great Britain there have not been very many engineering works of great interest carried out during the last year. The principal amongst those completed is the bridge over the Mersey at Runcorn, and the viaduct over the Solway. Of those in progress there is a bridge over the Trent at Nottingham, which I believe will be a very excellent example of its sort when finished. I may also mention the Chatham Docks. These works are on an extensive scale, and will no doubt be of great value to the service they are required Then there is the new dock at Hull, the Sunderland Docks, and the Tyne improvements. One of the most important questions that en-gineers have before them is that of town drainage and irrigation-a subject that has been particularly brought before us by our late president, who certainly has given us the benefit of his considerable practice in that branch of civil engineering, and for which we have much to thank him. The boldest of the proposed engineering works connected with England is that of passing under or over the Channel, for which we have three schemes, i.e., by means of a bridge, a tunnel, or a steam ferry. The first of these I do not expect to see scarcely expect to have been foreseen; for, after would be very desirable. I see no reason why ferry. The first of these I do not expect to see all, an engineer is but a human being, though they should not be tried. A light iron structured out; the second I believe to be quite practicable, the cost appearing the great objection; the third seems to me the most practical proposition, and I have no doubt would be found of great service to the public. On the continent, during last year, there have been some remarkable works completed, and many in progress, and if peace continues, and Spain settles down to working instead of fighting, I think we may reasonably expect a considerable advance in engineering works in that country, where there is a considerable field for engineering of all kinds; in Turkey, also, railways more particularly, improvements are much wanted. Then there are the Wallachian lines to be completed, and I understand some large contracts have lately been taken in that part of the world by English contractors this year. In Russia there will be heavy railway works in progress; Italy and Sicily will possibly add something to the European railway system.

The most remarkable railway work opened for traffic during the last year, is that over Mont Cenis, and, in spite of differences of opinion as to details in working, it must be considered a great engineer ing achievement. Its rival, the Mont Cenis tunnel, is gradually progressing towards completion, and when it is done, will solve the problem of under versus over mountain travelling. Bridge engineering has also been represented by some very fine, and, in some cases, novel structures. Perhaps the most novel, and certainly one of the finest, is that over the Moldau, at Prague, on the rigid suspension principle, which seems to be very successful; and I am very pleased to remark that Mr. Ordish, the engineer of this bridge, an old member of this Society, and one of its past presidents, has been presented by the Emperor of Austria with the gold medal of Arts and Sciences of that country on the opening of the bridge, and one of our prize-men (Mr. Wessely) with the gold order of merit, for the part he has taken in the con-struction of the bridge. One of the finest rail-way bridges in Europe has been constructed over the Rhine, at Kuilemburg, in Holland, which does great credit to its engineer and those who have carried it out. Its construction is, doubtless, fami-liar to you all, through the medium of the London scientific papers. It is remarkable for its large span of 492ft. in the clear. Among very numerous great European works in progress, may be mentioned the docks at Havre, which will, I understand be very fine when completed; and the drainage works and the canals in Holland.

Let us now travel eastward, and, crossing into Africa, we come to one of the grandest works of modern times—the great ship canal across the Isthmus of Suez. Already a small schooner, "La Levrette," has made a passage by the canal across the Isthmus; and I learn, on the best authority, that in about six months it is probable vessels of the largest size will be able to pass through the Isthmus from sea to sea. If this is realized, what a great engineering triumph it will be; perhaps even altering the fortunes of nations. Certainly, it will make a great difference in our Indian trade, but time will soon show; and it is scarcely worth theorising when we shall so shortly know what the result will be.

In India, again, what a great revolution engineering is effecting in that vast empire, and what an immense amount of work there is yet to be done in every branch of our profession; and, from what I can learn, there is now a great want of engineers in India, preventing works already proposed from being carried out. There are many difficult problems in engineering to be solved: one, I may mention, that appears to be more than ordinarily so, and which has yet to be overcome—I allude to the bridge over the Hooghly, which has taken up the attention of many engineers for some time past, without any practical result. Still there are works progressing of very great extent, in which there are many difficulties, taxing the skill of the engineers in every way. Take, for instance, the Great Indian Peninsular, the Bombay and Baroda, the Great Southern of India, and other railways; the dock and harbour works at Bombay and other parts of India, the progress of which we get reported to us from time to time.

Telegraph engineering is extending most rapidly, and ere the end of this year we may expect that the French Atlantic cable will be laid, forming another link between the old world and the new. And I believe that the time is not far distant when we shall have communication by telegraph with China and Australia. One seems to suggest the other, as it would doubtless be via China that a telegraphic line to Australia would be laid. Then there are the North Sea cables, which will be connected with an overland cable and carried on to India

through Prussia, Russia, and Persia. More particularly concerning us here, is that our Government will, in all probability, this year arrange that the Postmaster-General will have complete command of the telegraphs in this kingdom, which will be of great importance and value to the public in general, and I hope to see before long telegraphy as cheap as postage.

Engineering goes hand in hand with civilization, and, as we have seen, the rapid alteration railways have made in changing the aspect of towns and villages in England, and even the manners and customs of their inhabitants in many ways, so can we imagine the great alterations that will take place in India, when railways become common, and good roads and bridges abound in every locality. alterations will probably extend to China, and that curious race become more civilized, be better known to us, and their barbarous customs discontinued. In Australia, also, engineering is There are even now many large progressing. works necessary for the benefit of its inhabitants generally, and, as the population increases, will become absolute necessities. In America, since the late sad warfare has ended, engineering has made a brisk recommencement in many places, and I learn, on good authority, that the great question of the junction of the Atlantic and Pacific Oceans by a ship canal across the Isthmus of Darien is again mooted, and that the American Government have actually sent a gentleman of high position to make negotiations and inquiries respecting its being carried out. Our transactions for last year will contain, in papers read by Dr. Cullen, an excellent account of all that has been done with regard to this grand project.

In railway and bridge works, American engineers have proved themselves remarkable for their boldness of design and rapidity of execution. Take, for instance, the suspension bridge thrown across the Niagara River last year, which has the tremendous span of apwards of 1,260ft., or nearly double the width of the centre span of the late Hungerford Suspension Bridge. And we read of still greater spans as being proposed and probably carried out. Then there is the proposed bridge carried out. over the Mississippi at St. Louis, which will be a novelty in bridge building, as it will consist of three arches constructed in steel, the centre span of which will be 515ft., or some 35ft. wider than twice the span of the centre arch of Southwark Bridge. Some of the railways constructed with great rapidity (although it must be borne in mind that the style of work is totally different to that prevailing in England), and great ingenuity has been shown by the manner in which American engineers have passed their railways over most difficult countries. Both in North and South America there is a vast field for engineering enterprise in all its branches. Also in Canada it is known there are many important works required that sooner or later must be carried out.

I have not perceived anything particularly novel that has been introduced into civil engineering of late, although I must not forget to mention fact that, instead of building docks abroad, they built at home, and sent abroad to be ed in position. I instance the Bermuda float placed in position. I instance the Bermuda float dock, built in the Thames, now lying in the Medway, which leaves for its destination early this year; also a floating dock for Bombay. In foundations—which are the most important studies of an engineer—cylinders and screw-piles seem to be the favourite methods at present for bridge foundations, piers, and other works in water. In the London district, it seems the general opinion that, for large buildings, it is necessary to go down to the London clay for a foundation. I cannot perceive the absolute foundation. I cannot perceive the absolute necessity for this, and I think in many cases it might be avoided, at a great saving in cost. In mechanical engineering, improvements in detail appear to be constantly made. The great question as to the manufacture of steel seems to be still in dispute. We have not yet seen it used for any structure of importance in England at present, although I think it is probable we may do so before long. In cases where lightness is required rith strength it might be used very advantageously.

Hydraulic engineering has advanced to great perfection. Photography, which has been much improved during the last year, has proved invaluable to the engineer in illustrating the progress of works. Electricity—the most wonderful of all things applied for the use of mankind—has not yet been successfully used as a motive power; a single idea might revolutionize the whole of our present practice. Civil engineering is the application of natural philosophy, and it is by studying the great

laws of nature that we may hope, no matter by how small advances, to improve our profession.

In conclusion, let me particularly urge upon you, the members and associates of this Society, the necessity of earnestly working for its advancement. By becoming members, you show that it has your good wishes; but it wants more than good wishes—it wants your working assistance to further its objects. By attending its meetings you show a disposition to support those who are working for it; and by contributing papers, a willingness to give the knowledge you possess, not only to the Scoiety, but to the profession generally.

#### TELEGRAPH WIRES IN ARCHITECTURE

THE courts of law stubbornly set themselves against innovations, but in the end they give way to the result of established practice. It was only in the reign of Charles the Second that they came to a knowledge of bills of exchange, and they afterwards advanced to bankers' cheques and crossed cheques. They have latterly found out the Stock Exchange has been in existence for some time. Some solicitors are still wary of envelopes, and others doubt as to press copies of letters, preferring a law stationer's copy; but many believe in the penny post and in telegraphs. So, too, in the course of time, will some architects come to an after knowledge of many things which have been going on for some time, including a provision even for letter boxes. In this day, inventions disturb us in a pantomimic way. The telegraph was at first tolerably unobtrusive. It confined itself to railways, but having crept into towns, it jumps across the house-tops in various directions, without any regard to symmetry, and its wires are no more ornamental than clothes' lines, nor its posts than washerwomen's poles. The wires will go on, and their existence must be acknowledged. Our predecessors acknowledged weather cocks, and made N. E. W. S. ornamental. Is it not time for the architect to determine how far he can prevent the spider's web of telegraph wires from injuring his work? It is not one light almost invisible wire, but four or five strained taut, or a good wire cable hanging in a curve from steeple with light wires looped on to it. The supports are unredeemed abominations.

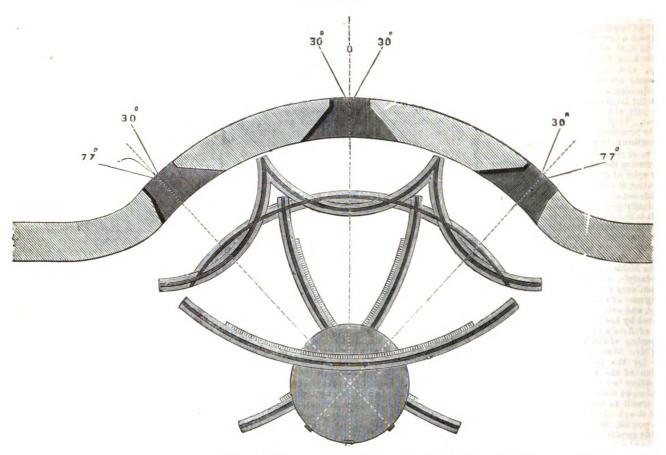

prevent the spider's web of telegraph wires from injuring his work? It is not one light almost invisible wire, but four or five strained taut, or a good wire cable hanging in a curve from steeple with light wires looped on to it. The supports are unredeemed abominations.

In the case of a railway bridge, a design is made in which every line is carefully studied, and then are put up the thick clusters of terminal and through wires, and pillars of signal stations, and the whole design is disfigured. If the bridge rests on iron piles, nothing would be easier than to have a telegraph pole in the line of each pier, but then the architect has never provided for it, and a workman is allowed to set up his posts at his own intervals—perhaps so many to the mile—and the wires he places at the height he thinks right, with any kind of insulators, utterly destroying the lines of a fine bridge. It is rare that the wires are kept below the parapets. Of course it is wrong for a casual workman to be allowed to do so, and directors and engineers never think of such things; but then they should be thought of in the design of the bridge, and Hungerford Bridge are all laid out as great monumental railway works, and anyone must know that on a railway there must be signal posts and telegraph wires. The lamp-posts are in some instances carefully provided for, and there are well-grouped clusters of lamps, but the other accessories mar the plan. It was possible, and may be still, so to place the signal posts, telegraph posts, and lamps, that while there is a group of signal posts at each end of the bridge, the telegraph posts if carried up, shall combine with the candelabra and correspond with the piers of the bridge, if placed on cast-iron piles or masonry. The Hungerford Bridge is one of the best arranged in this respect. The telegraph wires can very conveniently be kept below the line and worked into the details of the bridge. Where signal posts and telegraph columns with insulators are carried above, as they can be formed of metal, a

can very conveniently be kept below the line and worked into the details of the bridge. Where signal posts and telegraph columns with insulators are carried above, as they can be formed of metal, and as the insulators are of porcelain, it is quite possible to introduce gilding and colour, so as to compose with the decoration of the bridge.

There are also many cases of the erection of telegraph posts in towns which could be distinctly treated; in fact, it is only by such care that an architect can guard his work from after defacement by bell-hangers, gasfilters, decorators, upholsterers, and the whole horde of disfigurers. The Thames Embankment is very likely to have telegraph wires carried along it or near it, notwithstanding the subways, and then fresh lines will be introduced to compare with those of its mouldings. The Embankment has dealt rather recklessly with Somerset House and other buildings in its course, and we may look out for the like reckless dealing with the Embankment itself. There is an utter disregard in London of common administrative care, so that the natural artistic effect of our monuments is allowed to be tampered with indiscriminately, and the stock of our artistic wealth destroyed.—"Building News."

#### TURNTABLE SYSTEM OF WORKING BROADSIDE GUNS.

#### WORKING HEAVY GUNS.

WORKING HEAVY GUNS.

THE engravings on page 61 are illustrative of the system of working heavy guns on the broadside as proposed by Captain Scott, R.N., and adopted in the "Hercules." The problem to be solved is simply to obtain the greatest range of fire with the fewest guns, and the solution has been thus worked out. Our engraving shows such a casemate as is carried by the "Hercules." Ports worked in the side of the casemate permit a lateral fire, and ports in the thwartship bulkheads permit the guns to be fired nearly ahead or astern. This the guns to be fired nearly ahead or astern. This has already been done in the "Pallas" and "Research," and is found to be objectionable in several respects. Guns cannot be worked in both the corner ports, as we may term them, at the same time, as there is not room. It is therefore necessary to provide means by which a single gun can be transferred at will from one port to the other. Such an object is ordinarily effected in the following way:—The gun carriage runs on a slide, which slide is a parallelogram made of timber or iron, supported in its turn on small rollers, which run racers or arcs of metal secured to the deck. From the forward end of the slide proceeds a V-shaped piece of iron, the ends of the V being jointed The apex of the V is provided with an eye which fits down on a tapered pin in the centre of the port, and round this pin as a centre the slide, and with it the gun, can be made to radiate each way through an arc of about 30deg. The gun is principally secured by this pin and the V flap. Now, in order to transfer the gun from one port to the other, it is obvious that the V must be lifted off the pin, and the gun brought round by tackles until the eye in the V coincides with the pin in the second port. Even in calm weather this would not be very easily effected, as the eye just fits the pin, and it is no easy matter to move a dead weight of eight or ten, much more of twenty, tons to a quarter of an inch, and in rough weather it could hardly be an inch, and in rough weather it could hardly be effected at all, as the gun would be left comparatively uncontrolled. In order to provide for this, a second V is fitted to the rear of the slide when it is required to shift the gun, and the eye in this being dropped on to a pin in the deck inboard, the leading V is cast free, and the gun slide is then made to turn on its heel and radiate round to the other port, when the leading V is dropped on

to its pin and the rear V removed. The gun is then worked in its new position as it was in the old. In practice this system of movement is found to work unsatisfactorily in the case of all but small guns. The operation is tedious, uncertain, and dangerous at the best of times at sea, and in heavy weather it is highly imprudent to attempt

This difficulty is overcome in the following manner by Captain Scott. In the first place, the pins and V-pieces are entirely suppressed; just inside the ports are fitted gun-metal racers 1 1, shown in section in the side view of the gun slide. To the leading end of the slide a small roller is fitted, which bears against the raised flange of the racers 1 1, and being caught under the upper horizontal flange, prevents the slide from jumping up er running in, in which latter purpose it is aided by the flanges on the trunnions of the slide, as shown in the sectional elevation. By taking out a key, B can be turned up on the horizontal pin, and the slide so far left free. The gun will radiate round either port as a centre in the ordinary way, travelling on the racers 1 1, G G. It remains to be seen how it is to be transferred from one port and set of racers to the other port and set of racers.

In-board, and at a point equidistant from both ports, is fitted a small turntable let into the thickness of the deck, so as to be flush with its upper surface. The construction of this table will be understood from the sectional elevation. It carries a portion of one racer, and by causing this table to make a portion of a revolution, either one are or the other can be rendered perfect, or both broken. Supposing the gun is to be moved from the side to the front port, it is first run in until nearly over the turntable, in order that its muzzle may clear the ship's side; its entire weight is then borne by the turntable; B is then cast loose, and the turntable is caused to partially rotate, carry-ing round the gun until the section of racer carried by the table completes the racer belonging to the forward port; B is put in gear, the forward trunnions brought to bear on their racer, and the thing is done. If thought necessary, a subsidiary racer 2 may be introduced to give more security to the gun when being swung from port to port. Nothing can be more simple than the entire arrangement, and its superiority, not only over the system of transfer which we

first described, but over all other methods of working heavy guns on the broadside yet proposed, is apparent at a glance. The operation of transfer is exactly identical with that performed daily at every railway terminus in the kingdom when a locomotive is shunted by means of a turntable; and there is no reason to doubt its complete success. In our engraving, we have shown a 600-pounder gun on one side, a 9in. 12-ton gun on the other. The system is equally applicable to both, or to the 18-ton 10in. guns.

Before concluding, we may direct attention to an important development of this system of transfer. With a given weight of armour it is well known that a greater number of guns can be protected on the broadside than in turrets. But whereas the turret guns can range nearly round the horizon, when masts are dispensed with, guns in broadside when masts are dispensed with, guns in broadside ports can only be trained through an arc of about 60deg., and they cannot be worked satisfactorily at the maximum degree of training, as the crew are in each other's way. It is proposed, however, to construct casemate ships as shown in the illustration at page 61. The casemate might be so arrested to its construct which is the chick but the construct of the const ranged that it would fall within the ship's bul-warks turret fashion, even at the place of maximum projection. The number of guns to be carried would vary with the size of the ship. The details of the mode of working the guns will be understood from what we have already said. The racers, racks, and turntable would be flush with the deck, and the extreme range of each gun would be about 154deg. instead of 60deg. By carrying the armour of the casemate inboard, less strain would be thrown on the hull, and the ship would be rendered steadier in a sea way. A light living deck forward and aft would provide ample accommodation for the crew, and might be knocked to pieces in action without impairing the efficiency the ship at the time, or endangering her safety; and there can be no room to doubt that an exceedingly safe and serviceable cruiser could be thus produced.

In 1867, the number of emigrants who left the Mersey was 115,681. In the year just concluded, the number was 129,337, or an increase of 13,656 on the year. Of the total number, 102,323 were for the United States, 15,409 for Canada, 1,601 for Victoria, and \$40 for South America.

SAVING LIFE FROM SHIPWRECK IN 1868

THE past year will long be remembered as one of the stormiest on record. It is, however, satisfactory to find that the year will also be well remembered for the great exertions which have been put forth to save shipwrecked persons. appears that during the past twelve months the boats of the Royal National Lifeboat Institution have been instrumental in saving, during boisterous weather, the crews of an unprecedented number of distressed vessels on the coasts of the British Isles. From a long list now before us, we find a total of 558 lives rescued by the lifeboats of the Institution, in addition to 23 vessels saved from destruction. During the same period, the Lifeboat Institution granted rewards for saving 259 lives by fishing and other boats, making a grand total of 817 lives saved mainly through its instrumentality. In the same period, the crews of the lifeboats of the Society, at a very large expense, have either assembled or put off in reply to signals of distress 142 times to ships not eventually requiring their serrices. It often happened that on these occasions the lifeboat crews had incurred much risk and exposure throughout stormy days and nights. number of lives saved either by the lifeboats of the Institution, or by special exertions, for which it has granted rewards since its formation, is 17,795, for which services 90 gold medals, 798 silver medals, and £28,906 in cash, have been given as rewards.
When we remember that nearly every life saved by lifeboats has been rescued under perilous circumstances, it will at once be seen what great benefit has been conferred by the Lifeboat Institution, not only on the poor men themselves and on their country, but also on their wives and children, who would otherwise be widows and orphans. Since the beginning of the year, the Institution has spent £18,818 on its 194 lifeboat stations on the coasts of England, Scotland, and Ireland: and since its first establishment in 1824 it has expended £212,820 on its lifeboat stations. strongly urge on all who recognize the sacredness of human life, the duty, and even the privilege to help forward the lifeboat work, a work which has hitherto been manifestly blessed by Providence, and which has brought relief to many thousands of men, who, instead of being this very day valuable members of the community, would have been long ago engulphed in the raging waves of the tempest, leaving, in many cases, widows and orphans to suffer not only the misery of bereavement, but the pangs of destitution. We will only add, that contributions are received for the Lifeboat Institution by all the London and country bankers, and by its secretary, Richard Lewis, Esq., 14, Johnstreet, Adelphi, London.

#### COPPER PRODUCE.

THE production of copper in the United Kingdom and the value of the product continue to decrease. In 1857, 250,871 tons of the ore were raised, and were found to be of the value of £1.560,922; in 1867 only 158,544 tons were raised, and their value was but £699,693. The metallic copper produced amounted in 1857 to 17,375 tons, of the value of £2,154,500; in 1867 it was only 10,233 tons, and of the value of only £831,761. This decline has been chiefly in the last seven years. The quantity of the ore raised in 1860 was as much as 236,696 tons and its value was more than double the value of the 158,544 tons raised in 1867; and the metal produced in 1860 was as much as 15,968 tons, and its value more than double the value of the 10,233 tons of 1867. The average price obtained for Cornish copper was £6 8s. 6d. in 1857, £5 19s. in 1860, from which last date it gradually declined until it reached £4 7s. in 1867. Of last year's 158,544 tons of copper ore, 88,660 tons, of the value of £413,876, were raised in Cornwall; 31,311 tons, of the value of £144,773, in Devonshire, more than 20,000 tons from the Devon Great Consols Mine; 8,406 tons, of the value of £26,655, in Wales; 12,482 tons, of the value of £83,529, in Ireland, chiefly Cork and Waterford. Of the 10,233 tons of metallic copper obtained, 5,995 tons, of the value of £494,179, were from the mines of Cornwall: 2,055 tons, of the value of £169,114, from Devonshire; 452 tons, of the value of £34,460. from Wales; 1,189 tons, of the value of £93,874, from Ireland. The number of mines returned was 188 in 1857, 170 in 1860, and 164 in 1867.

THE total cotton receipts at all the U.S. Southern ports from September 1 to the close of 1868 were 1,067,549 bales, as compared with 947,092 bales during the same period of 1867.

#### PHOSPHATES IN AGRICULTURE

UCH attention has been given of late in France A to the treatment of coprolites and other bodies containing phosphates applicable as manures; and an agricultural writer, M. Adolphe Bobierre, has given, in the "Journal de l'Agriculture," of Paris, an agricultural without, given, in the "Journal de l'Agriculture," of Paris, an account of the methods in action, and experiments in connection with this important question. "Charges from tropical regions," says M. Bobierre, "Guanos from tropical regions," says M. Bobierre, bone ashes from the pampas of Central America, phosphorites and apatites from Spain and Portugal, coprolites and nodules from the carly limestone formation, the refuse of sugar-houses and refineries. gelatine and button manufactories—everything, in fact, which contains phosphoric acid in any quant is now the object of serious, and generally profitable, application. Guano is obtained from the giddy heights of the mountain peaks in sight of the coast of Bolivia, while in the Ardennes it is found worth while to remove sixty or more metres of argillaceous earth to obtain a ton of phosphated nodules, which, when washed and pulverized, rival bone-black." The writer recognizes the great activity of English chemists and agriculturists with respect to phosphates and the production of superphosphates, and the immense services which they have rendered; but adds, that the manufacture of superphosphates cannot be said to be perfect so long as the sulphuric

With respect to what has been done in France. M. Bobierre gives some interesting examples. The nodules of phosphate of lime have been largely employed in Brittany, in the cultivation of the Landes, in the place of bone-black, which has been used largely for thirty or forty years; this has created a very important employment; and we are told that wery important employnent; and we are told that many of the dealers in manure have entirely given up the sale of bone-black for that of pulverized fossil phosphates. Attempts have been made to separate the phosphates from the thirty per cent. or more of silicious matter with which they are associated, and also, on the other hand, to produce mixed manures, in which the activity of the phosphoric acid should be brought out in the most effective manner; these desiderata have been realized with considerable success. One process is to treat the rough phosphates with chlorohydric acid, and to recover the acid by evaporation. Another process mentioned is to convert the nodules into metallic phosphates by calcination in a blast furnace, in contact with iron ore, and then to transform the metallic phosphites into alkaline phosphates by the action of chloride of sodium at a high temperature. A third method is to attack the fossil phosphates by many of the dealers in manure have entirely given A third method is to attack the fossil phosphates by means of chloride of manganese with an excess of acid, obtained from the manufactories of chlorides for bleaching and other purposes; and, lastly, the fossils are sometimes simply calcined with gas tar or other similar substances.

The writer says that the results of the above methods and experiments have confirmed him in a reviously expressed opinion, that if the nodules be previously expressed opinion, that if the normies be reduced to a powder, and the powder exposed to the action of the air, and applied to soil requiring the application of phosphoric acid, the fossil phosphates are perfectly assimilated; and, further, that a mixture are perfectly assimilated; and, further, that a mixture of fossil phosphates with ordinary manure yields the most admirable results, even in the case of old cultivated lands. "Let farmers only adopt the habit of throwing fossil phosphates under the animals," says the writer; "nothing more is required." M. Bobierre seems to consider the treatment of nodules by means of acids as scarcely called for, but recommends this process strongly in the case of phosphorites, apatites, and certain phosphatic guanes found almost in a vitrified condition. With respect to France, the writer observes that phatic guanos found almost in a vitrified condition. With respect to France, the writer observes that within a short distance of the coasts of Spain and Portugal, where the tribasic phosphates, containing 70 to 90 per cent. of phosphate may be obtained at the rate of 2s. 6d. to 3s. 4d. per cwt., enormous quantities of hydrochloric acid are wasted, and worse than wasted, by being allowed to vitiate the air; the town of Marseilles, which converts large quantities of sea-salt into sulphate of soda, is destined to waste annually fifty millions of pounds of hydrochloric acid, which could, with very little trouble, be made

acid, which could, with very little trouble, be made to dissolve the natural phosphates.

In connection with the above may be mentioned a communication made by MM. Dusartand Pelouze, to the Academy of Sciences. One of these gentlemen, in a work entitled "Researches on the Assimilation of Phosphate of Lime," showed that, when acted upon by the gastric juice and very diluted lactic acid, phosphate of line underwent partial decomposition, yielding a mixture of lactate and lactic acid, phosphate of lime underwent partial decomposition, yielding a mixture of lactate and acid phosphate of lime; this led to experiments on the action of carbonic acid on phosphate of lime, with the view to throw some light on the obscure with the view to throw some light on the obscure subject of the assimilation of phosphate of lime by plants. In 1864, M. Dumas noticed that carbonic acid was a solvent for phosphate of lime, by the effect of seltzer water, in softening ivory and abstracting all the calcareous phosphate therefrom Other chemists have regarded this action as merely a solution of the salt by the carbonic acid, but MM. Dusart and Pelouze are of opinion that the action referred to is of a more complicated character,

and that the acid absorbed gives birth to new

products.

These gentlemen treated gelatinous phosphate of These gentlemen treated gelatinous phosphate of lime with water, saturated with carbonic acid, and found that after some time the acid had partly disappeared, and the phosphate itself had notably diminished; the transparent liquid obtained by filtration deposits by heat a crystalline precipitate, composed of phosphate and carbonate of lime. A series of nice experiments is then detailed to prove that bibasic phosphate of lime is produced, either by the action of carbonic acid on tribasic phosphate of lime, or by that of acid phosphate of lime on the carbonate. On this principle, say MM. Dusart and Pelouze, we have been able to produce it, by the following economic practical method, in such a state of purity that, compared with superphosphate, it contains double the active power in an equal volume. contains double the active power in an equal volume. The matter to be dealt with—natural phosphates, coprolites, bones or animal charcoal—are placed in wooden vats lined with lead, communicating with each other and covered with a mixture of water and acid; any acid will effect the transformation, but we prefer hydrochloric acid or the weak nitric acid, which is wasted in so many works. When the acid has macerated in one vat, we remove it into a second, and if necessary a third, and the clear liquor is finally treated with pulverized carbonate of line; effervescence is moduled analysis and analysis analysis and analysis analysis and analysis analysis and analysis analysis and analysis and analysis analysis and analysis and analysis analysis and analysis analysis and analysis analysis and analysis analysis analysis analysis and analysis anal finally treated with pulverized carbonate of line; effervescence is produced, carbonic acid is thrown off, and a precipitate of white crystalline bibasic phosphate of line is thrown down. When sufficient carbonate is used, the liquor is deprived of all the phosphate that it contains, and the precipitate is easily dried and washed.

There facts early the chamiets in question to

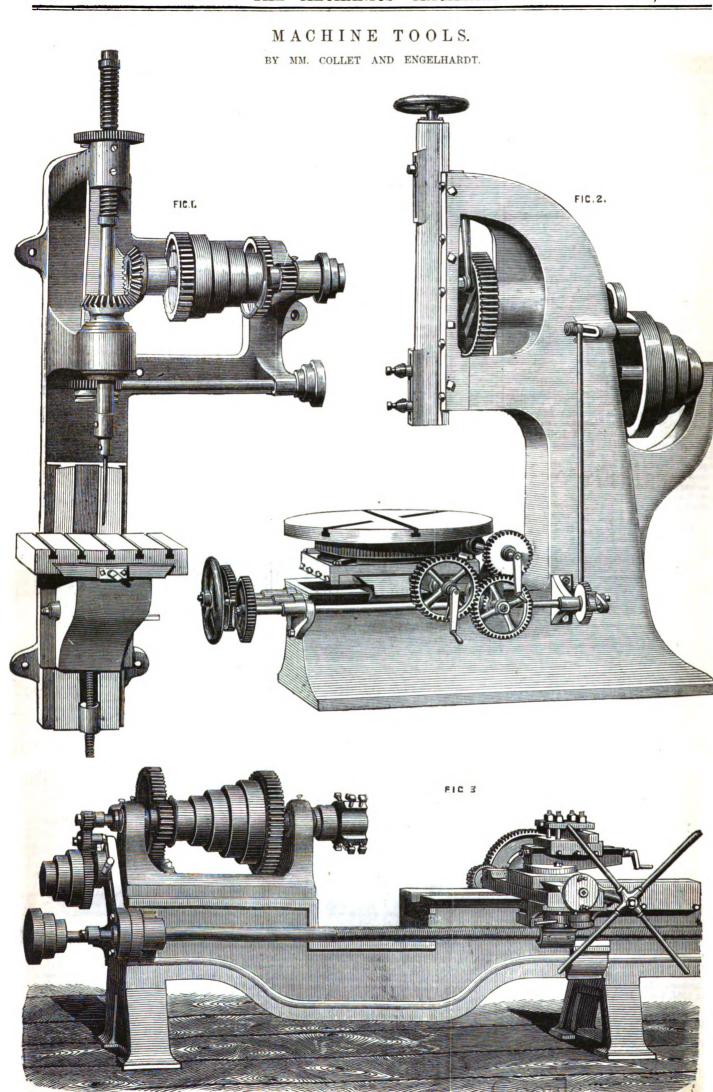

easily dried and washed.

These facts enable the chemists in question to form the following hypothesis concerning the manner in which nature enables plants to take up phosphates. It is evidently in the soluble form that the plant uses them for its nutrition; the common phosphate of lime, completely insoluble in water, should therefore be rendered soluble. Carbonic acid dissolved in water performs this first transformation in the same way that the stomach of an animal renders it soluble by converting it into acid phosphate and lactate of lime. The enormous quantity of superphosphate of lime employed in England, a practice now adopted in France, is quoted in support of the above theory. The superphosphate, which, according to these gentlemen, is only an impure acid phosphate of lime, when introduced into the soil, attacks the carbonate of lime, under the influence of lumidity, and is thus transformed into a bibasic phosphate. As it is impossible to imagine that any substance can be entirely absorbed by plants during the plant uses them for its nutrition: the common phosphate. As it is impossible to imagine that any substance can be entirely absorbed by plants during the first few days of its being spread upon the ground, if the superphosphates do not undergo this transformation, which diminishes their too great solubility, they would certainly be carried down to the sub-soil by the first heavy rain, and part of their value thus lost. The facility with which bibasic phosphate of lime can be produced in a state of great purity renders it a promising substitute for common phosphate, and even for superphosphate, which is always mixed with a large proportion of which is always mixed with a large proportion of other matters, which have no value as manure, and of which the cost of carriage is, therefore, at any rate, a loss to the farmer.—"Society of Arts Journal."

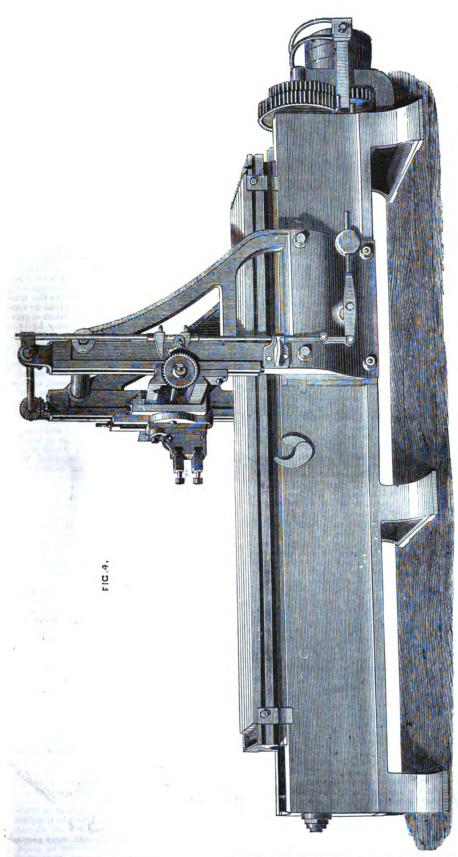

#### PREPARING CABINET SPECIMENS.

T a recent meeting of the Manchester Literary and Philosophical Society, Dr. Alcock showed a preparation preserved by corrosive sublimate in a manner which he recommended for fine dis-The preparation had been kept in an open cup for twelve months, simply water being added occasionally to supply what was lost by evaporation. The advantages of the plan were, very perfect preservation, no necessity for closing u) so that the specimen could not be got at, no fear of losing a valuable dissection from accidental evaporation, as where spirit is used, and cheapness. The method adopted was to propure a saturated solution of corrosive sublimate in alcohol, and when a dissection in water is in progress a small quantity, as half a teaspoonful, of the solution is to be added from day to day if the slightest appearance of putrefaction is observed, but no more of it is used than is absolutely necessary, and by the time the dissection is completed, the specimen has become imperishable, from the union of the corrosive sublimate with the tissues, and it may then be kept in pure water, either open or mounted in the

A CELEBRATED cliff in Denmark, the "Queen's A CELEBRATED cliff in Denmark, the "Queen's Seat," has just fallen bodily into the Baltic from a shock of earthquake. The rock, about 400ft, high, was an object of great interest to tourists from the magnificent view to be had from it. On a clear day, Rogen and the coast of Pomerania could be plainly seen. Everything has disappeared except some masses of chalk which form a sort of island near the shore. No life has been lost, but the inhahitants of the coast of the coa the neighbouring villages were terrified at the noise produced, and which lasted several seconds.

#### MACHINE TOOLS.

MACHINE TOOLS.

IN the annexed engravings we illustrate a set of machine tools, by MM. Collet and Engelhardt, mechanical engineers, of Offenbach. These tools are well worthy of notice as good plain pieces of work, well designed and carefully executed. They have the stamp of English models on them, but it is scarcely possible to find an original pattern of a machine tool out of England, though there are now perhaps as many makers of such articles abroad as at home. The foreign workman has not

yet the self-reliance which long education and the successive improvement of two generations hav given to our best hands, but they are rapidly improving, and are just as well able to execute work up to a moderate standard of excellence as we are. Messrs. Collet and Engelhardt's tools are really good examples, and when we consider that in the district from which they come machine toolmaking was unknown ten or twelve years ago, we must accord to the firm great credit for the exhibits they have turned out. Fig. 1 is a wall drill with rising table, and, of course, self-acting motion.

Fig. 2 is a slotting machine with a revolving table, self-acting in all directions; this tool has the guide bearing in the slides throughout almost its entire length. Fig. 3 is a self-acting slide and screw-cutting lathe, the sliding gear being worked on the central rack, and the screw-cutting only is done by the lateral regulating screw. It has 13in. centres, and about 10ft. bed. This is a kind of tool in which small German mechanics delight; it is a multum in parvo, in fact, sliding longitudinally and transversely, turning and boring, and cutting right and left-hand screws. Fig. 4 is a conveniently-sized planing machine with a bed of 8ft. by  $2\frac{1}{2}$ ft. The motion is by a rather quick screw in cast steel, the gearing at the end of which, as will be seen by the engraving, admits of a double speed return motion.

#### RENDERING CASKS IMPERVIOUS.

A mimproved method of treating brewers' casks, so as to render them impervious, has lately been patented by Mr. J. D. Scally, of Moorstreet, Burton-on-Trent. To this end he treats them with pure paraffin, which he applies in several ways. In one instance, he heats the cask by fire or by filling it with hot air, and then runs some melted paraffin into it, rolling it about so that the paraffin may be brought into contact with the whole of the inner surface. Supposing it to be necessary to thoroughly impregnate the pores of the wood with the paraffin, steam under considerable pressure is turned into the barrel. To effect this a steam pipe in connection with a boiler is fitted by a close joint to the bung-hole of the cask, and steam is turned on for a short period. A more elaborate, but yet more perfect way of curing casks, however, is the following, which Mr. Scally finds the preferable of the two. The cask is first heated by hot air, and then exhausted so as to form a partial vacuum inside the cask. This is easily done by applying a pipe fitted with a tap to the tap-hole in the head of the cask while the cask is hot, and connecting the other end of the pipe with an air pump, and so exhausting the cask of air. A jet or spray of melted paraffin is then admitted to the interior of the cask through the bung-hole by means of a close-fitting pipe connected with the vessel holding the melted paraffin. The hydrocarbon will then immediately fill up the pores of the wood, and will render it impervious. This will be readily understood from the processes used for preserving timber, in which cases the timber is placed in a receiver, the air exhausted, and the preserving material injected, when it is rapidly absorbed by the wood. Of course, casks can be preserved by taking out the head, heating the interior, and laying the melted paraffin on with a brush, but this is the least preferable method of the three we have described.

on with a brish, but this is the least preferable method of the three we have described.

The practical result of the application of this principle is found by Mr. Scally to be that, in the first place, the cost of filling up is avoided in breweries, all loss by absorption being prevented. Beers having to remain in cask all the summer are better preserved; the air being thoroughly excluded, the alcohol cannot acidify. Further, casks thus treated do not get fusty from wet, dirt, or exposure; the hydrocarbon being perfectly liquidigith, the germs of fust are unable to impregnate the wood. Fusty, woody, sour and stinking casks also will be cured by the application of Mr. Scally's process, as the contents of the cask will be thereby perfectly isolated from the fusty wood.

### ENGINEERING PROGRESS IN INDIA IN 1868.•

CHIEF among the characteristics of the year now so swiftly drawing to its close, is the full sanction accorded by the Government of India to the establishment of the best systems of irrigation and navigation works throughout its vast and industrial empire. It is not to be expected that the encouragement thus afforded would materially confer any benefit on the country within a few years, as such vast and gigantic schemes demand considerable time and space to produce the necessary and desired ends. It is our duty at the close of the year to which we have arrived, to do service to the country by consistent advocacy of right principles and the faithful pursuit of truth, to review the field of our united professional exertions, and to see what progress has been effected in India by our labours during the present year. The sanitary state of towns, involving the important questions of drainage, of water supply, of ventilation, the provisions of homes for the poor, and of hospitals for

• Calcutta "Engineers' Journal, December 1, 1868.

the sick, the construction of barracks for the European and native soldiery, communication of towns and of country, external and internal, by means of bridges, roads, footways, and railways, the defence of the great centrosof national life, involving questions of arms and fortification; the provisions for drought and famine, involving systems of irrigation and navigation to which we have already referred, and the direction of the intelligence and industry of the country in those channels which alone lead to a the country in those channels which alone lead to a sound and permanent prosperity, are the subjects to which, some have received careful attention, while others witnessed appreciable progress. The public mind is far more fully awake than at any former year to the importance of sanitary questions, and to the necessity of the construction of a permanent railway bridge across the Hooghly in Calcutta.

With reference to the new publishers for invited

With reference to the proposed schemes for irriga-tion and navigation in the Province of Bengal, those for the reservoirs at the river Selye in the district of Midnapore, canals of irrigation and navigation from the Damoodah river to Calcutta, systems of canals from the Gunduck river in the district of Tirhoot, navigation canal from Rajmahal on the Ganges to Calcutta, have been carefully investigated, and the preliminary surveys and levels taken during the year for the purpose of commencing with the execution of the necessary works. For the construction of the sixteen reservoirs in the district of struction of the sixteen reservoirs in the district of Midnapore, no less than 2,373 miles have been levelled, and are estimated to cost 4½ lakhs of rupees; the distributary channels at 4½ lakhs, and the entire cost of the project at 9½ lakhs. The quantity of land irrigable therefrom is estimated at 51,200 acres of paddy and 22,400 acres of cold weather crops; the entire cost of the surveying and levelling works being 8,715 rupees. The canal of irrigation and navigation from the Damoodah at Burdwan to Calcutta will be 100 miles. The surveys irrigation and navigation from the Damoodah at Burdwan to Calcutta will be 100 miles. The surveys and levels had been taken during the past year, and is estimated to cost, exclusive of works, 30 lakhs. The cost of the surveying and levelling work amounted to 17,850 rupees. The proposed canal is now in course of construction. The formation of a system of canals of irrigation and navigation from the Gunduck for the benefit of the three districts of Chumparan, Sarun, and Tirhoot, is one of the most important irrigational projects for of the most important irrigational projects for Bengal, as it would greatly relieve the distress and mitigate the horrors of famine, which is occasionally in those districts.

With respect to the project, 2,373 miles of surveying and levelling have been taken during the year; besides these, a detailed examination has been made besides these, a detailed examination has been made on both banks of the river with the view of determining the measures necessary for placing the embaukments in a complete state of efficiency. The entire cost of the work already done amounts to 25,914 rupees. The last project investigated this year in Bengal is that of a canal from the Ganges at Rajmahal to Calcutta, combining provisions for the irrigation of the district of Nuddea, and investigation into the feasibility of protecting them from the effects of such inundations as occurred last year; the work done being 454 miles of level and surveys, and its total cost 20,126 rupees. The first project taken up this year, in the province of Punjab, is for the proposed Sutlej canal, for which 1,193 miles have been levelled. The entire cost of the project is estimated at 2 crores of rupees. In the province of Oudh, 639 miles of levelling have been completed, and a rough prismatic survey of the province of Oudh, 555 miles of leveling have been completed, and a rough prismatic survey of 1,200 square miles of country finished. The result of the latter project has been the entire practicability of constructing a first-class canal for irrigation and of constructing a first-class canal for irrigation and navigation from the river Sardah, extending through the province and a portion of Bareilly and Shahjehanpore district, the entire cost of the work done being 5,000 rupees. Thus, we trust, after the careful investigation we have made for the introduction of the best systems of irrigation and navigation works throughout the important districts of India, that every successive year by the of India, that every successive year, by the judicious and diligent application of science to the our own interests, but greatly alleviate, if not altogether prevent, the horrors of drought and famine in this country.

The appointment of an eminent statistician to the office of the Imperial Sanitary Commissioner, to

The appointment of an eminent statistician to the office of the Imperial Sanitary Commissioner, to have the entire responsibility of registering births and deaths throughout the chief cities of India, anticipates well of the sanitary progress in this country. It is now a universally acknowledged fact that accurate statistics of mortality and diseases should constitute the basis of sanitary science, and are the only index of its progress. One of the chief duties of a statistician is to ascertain with precision the difference between the total number of births and deaths. and the difference between the numand deaths, and the difference between the num-ber of settlers and emigrants who come to the country to join in the great struggle for subsistence or for wealth, and of those who seek the comparative or for wealth, and of those who seek the comparative repose of a rural district after retirement from service; to these causes the actual increase or decrease of a given population is principally attributable. Another important duty connected with this office is to detect the causes of disease as arising rom drainage, water supply, and ventilation, which,

important as they are, must always be regarded among the many requisites to comfort and safety in city life.

Simultaneously with this office the Government of India has made the appointment of an experienced mining engineer in connection with the geological survey of India, for the purpose of determining with precision the mineral resources of India, improving and extending mining operations, and subsequently collecting and tabulating the mineral statistics of the country, which has been looked upon with great pleasure and satisfaction by the country at large. Taking into account the extensive geographical position of India, the economical development of its coal and iron mines, is a question of the highest importance, on which special attention and care should be exclusively devoted by the engineer on whom the appointment has this year been conferred, in order that the country should not at any time look for the supply of coal from other sources.

Regarding the construction of barracks for the accommodation of European troops throughout India, we are glad to learn, from the report of the precision the mineral resources of India, improving

India, we are glad to learn, from the report of the Inspector-General of Military Works, that the progress of works under his supervision has been, on the whole, satisfactory. Out of the entire amount of 10 crores of rupees, which have been reserved for military projects, an expenditure of 61 crores of rupees have been dealt with by the Government of rupees have been dealt with by the Government of India, with 3½ crores by sanctioned estimates, and 3½ crores by approved rough projects, and further that an expenditure of rather more than 3½ crores had been actually incurred. Nothing of any importance has been done in the province of Bengal, with the exception of the erection of new barracks for two batteries of artillery at Barrackpore, on which fair progress has been made. During the late threatened insurrection in British Burmah, several of the barracks at Thavet Myo have been completed on which fair progress has been made. During the late threatened insurrection in British Burmah, several of the barracks at Thayet Myo have been completed, and are ready for the occupation of troops in that town. In the presidency of Madras, the only important work done is the construction of barracks at Bangalore, on which considerable progress has been made. In the province of the Punjab, several of the barracks at Delhi have been completed, and have already been occupied; while at Moultan, Jullundar, and Peshawur, the progress of the works has been very satisfactory. In the north-west provinces, at Allahabad and Cawnpore, especially in the former city, great impetus has been afforded for the completion of the new barracks for a regiment of infantry and battery of artillery. In Oudh and Hyderabad, especially in the districts of Lucknow, Sectapore, and Fyzabad, great progress has been effected, while in the central provinces the improvements in the existing barracks at Jubbulpore have been completed, and at Saugor four commedious barracks are quite ready for the occupation of troops, and the new hospital for the infantry has been considerably advanced.

Regarding the Ordnance and Commissariat De-

Regarding the Ordnance and Commissariat De-Regarding the Ordnance and Commissariat De-partment, the buildings, consisting chiefly of gun-powder factories at Ishapore, are nearly completed; the gun carriage agency at Allahabad, and tannery the gun carriage agency at Allahabad, and fannery buildings at Cawnpore, on both of which considerable progress has been effected. The partial supersession of breech-loaders on an extensive scale may be regarded as a new era in the history of military engineering in India. This important invention is due to the fertile genius of Snider, and affords augmentation of approved strategic skill, and therefore gives us further impetus to the renewal of discussion on the merits of the invention. It is pretty well known that the distinguished artillerist discussion on the merits of the invention. It is was possessed of no claim whatever on the attention of the Home Government, for neither had he official connection, parliamentary influence, nor any qualification whatsoever, for dealing with a bureaucratic system. He had merely genius,—that practical genius which overcomes all insurmountable difficulties, detects a great want and private at the second which overcomes all insurmountable difficulties, detects a great want, and points out the mode of supplying it. We may well observe that the characteristic element of Snider's invention is the instantaneous extermination of a horde of combatants by the rapid breech-loading fire, having always at hand the necessary means of safety and protection to those engaged in operations. The introduction of the invention reflects great results at the extension of the invention reflects great results at the safety and protection. hand the necessary means of safety and protection to those engaged in operations. The introduction of the invention reflects great credit on the military authorities in India. Taking into consideration the actual condition of the country in a strategic point of view, it may be well to state that it is the first duty of those charged with the military defences of the country, and responsible for the expenditure of the large sums of money annually voted for that purpose, to see that at every moment we are up to the improvements of the day, to determine the best forms wood and iron can be framed for the sides of a vessel, to solve the questions whether penetration a vessel, to solve the questions whether penetration er smashing blows be the most efficient mode of er smasning plows be the most entitled induce of attack, and to decide on the best gun on either case, are points that well deserve all the care and cost for careful consideration. It is with this view that we recommend the formation of an institution similar to those in different countries of Europe, where strategic experiments are so advantageously conducted, and it is by this means at our command,

celebrated Whitworth for excellence in mechanical science is the result of that happy conception which science is the result of that happy conception which the distinguished mechanician entertains of the future pre-eminence in arts and manufactures of this country. Thus, we trust, that his munificent bequest may be followed by others in the same sphere of usefulness for encouraging the study and practice of the mechanical arts and sciences, and materially conferring benefit on the country by their absence.

Glancing over the improvements effected this Glancing over the improvements enecked the year, in railway traffic in this country, we may well state that the extension of the Punjab Railway from Delhi to Umballa, and the subsequent opening of the same by His Excellency the Governor-General in person, adds a fresh and important link of railway in person, adds a fresh and important link of railway communication in the Punjab; and, considering the character of the people we have to deal with at all times, and with the object of further increasing facilities of travelling, it is not to be wondered at that immediate steps should be taken for extending and completing the line to Lahore and other populous cities in that province.

#### REMARKS ON THE HYPSOMETER.

DR. HOOKER, in his travels in India, made extensive use of the hypnometer. D sive use of the hypsometer, and some of his remarks upon this instrument in his "Himalayan Journals" are peculiarly valuable, coming from a person of so much experience and so high a scientific authority. He says:—"The kettle used was a copper one, with free escape for the steam; it answered perfectly for all but very high elevations indeed, where from the water boiling at a very low temperature, the metal of the kettle, and consequently temperature, the metal of the kettle, and consequently of the thermometer, often got heated above the temperature of the boiling water. I found that no confidence could be placed in observations taken at great elevations, by plunging the thermometer in open vessels of boiling water, however large or deep, the abstraction of heat from the surface being so rapid, that the water, though boiling below, and hence bubling above is not puriferent of the same temperature. bling above, is not uniformly of the same tempera-ture throughout. From this it may be concluded that the boiler should be a covered vessel, made of thin metal, that the less water employed the better, that the thermometer should not have a metallic scale, but should be graduated on the tube itself; that the bulb should always be placed just above the water in the centre of the steam-space; and that the apparatus should be so proportioned as to boil the water in the shortest possible time. Good shelter and a steady fire should always be sought for. With regard to the formula employed for deducing the regard to the formula employed for deducing the altitude from a boiling-point observation, the same corrections are to a great extent necessary as with barometric observations; if no account is taken of the probable state of atmospheric pressure at the level of the sea at or near the place of observation, for the hour of the day and mouth of the year, or for the latitude, it is obvious that errors of 600ft, to 1,000ft, pay he computated. For reading latitude, it 1,000ft. may be accumulated. For practical purposes, it may be assumed that the traveller in countries where boiling point observations are most desired, has never the advantage of a contemporaneous boil-

ing-point observation at a lower station.

"The mean annual and mensual barometric pres-"The mean annual and mensual barometric pressure is now pretty well determined for every parallel of 5deg, from the equator to 60 N. and S. at sea, thanks to the labour of Maury, Fitzroy, and others; this value should, therefore, be employed in the absence of a more certain approximation to a simultaneous observation at the sea band of the statement of the seasons absence of a more certain approximation to a simul-taneous observation at the sea level, or at a lower station the elevation of which is known. If within the tropies, the mean monthly pressure should be corrected for diurnal range. The temperature of the sea level should be assumed in a similar manner when it is not absolutely known for a station of reference. When the data of the upper and an appro-priate lower stations are carefully observed with varipriate lower stations are carefully observed with priate lower stations are carefully observed with verified instruments, experience seems to prove the most complete accordance of the results of hypsometric measurements with both barometric and trigonometric measurements. With the drawbacks attending want of precise observations at a lower station, the results of Dr. Hooker's numerous calculations show that the error of the hypsometric method will be within 100ft, generally for all elevations. So impressed, indeed, was Dr. Hooker with the satisfactory results of his own observations made in 1434 50. impressed, mated, was Dr. Hooker with the satisfac-tory results of his own observations, made in 1848-50, with instruments which would now be considered objectionable, that he writes:—'For the elevation of great mountain masses, and continuously elevated of great mountain masses, and continuously enevaced areas, I conceive that the results are as good as barometrical ones; for the general purposes of botanical geography, the boiling-point themometer supersedes the barometer in point of practical utility, for under every advantage, the transport of a glass tube full of mercury, nearly 3ft. long, and cased in metal, is a great drawback to the unrestrained motion of the traveller.""—" Horological Journal."

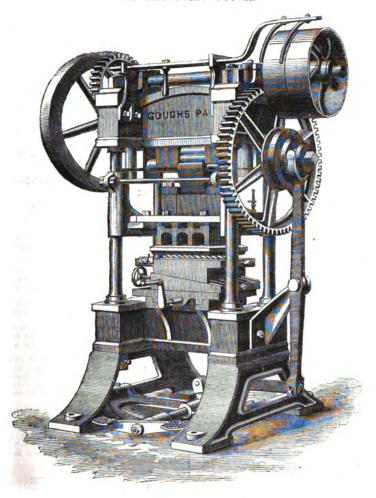

where strategic experiments are so advantageously conducted, and it is by this means at our command, that improvements in arms and fortifications can gradually and successfully be introduced.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending January 16, was 6,051. Total number since the opening of the Museum, free daily (May 12, 1858), 1,482,377.

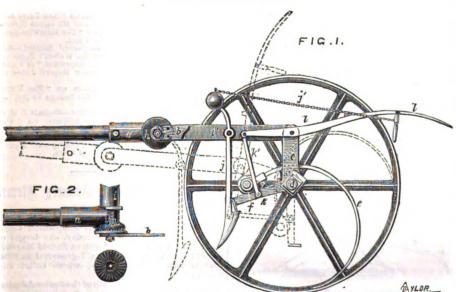

#### PATENT ROTARY ARMING PRESS.

BY MR. JOHN GOUGH.

#### HORSE RAKE.

BY MR. ROBERT BOBY.

### ROTARY ARMING PRESS.

IN our first number for the present year, we described and illustrated some improvements paper-cutting machinery, by Mr. John Gough, Kirby-street, Hatton-garden. We now place of Kirby-street, Hatton-garden. We now place before our readers particulars of another machine by the same ingenious inventor. This is a patent rotary arming press for producing devices on bookcovers, &c., and is of great importance to bookbinders. The distinctive features of this press are, facility for feeding, solidity of design and construction, and economy of floor space. Our engraving above represents a large sized press, to be worked by steam power. In this machine

the shaft carrying the strap pulleys is placed upon the top of the press. At one end of this shaft is fixed a toothed wheel geared into the flywheel, and greatly augmenting its speed. On the other end of this shaft is fixed a small pinion, geared into the large wheel running loose upon the eccentric shaft. This wheel is fitted with a clutch, sliding on the square end of the escentric shaft, which clutch is worked by the foot, and stops or starts the tool instantly. The eccentric shaft is placed under the head of the press, and the eccentric (which is a solid part of the shaft) is supported on each side by extra bearings. The working on each side by extra bearings. The working parts of this shaft which receive the pressure are in sight, and they, with the lower end of the con-

nection between the eccentric and heater box, are

self-oiled in the most perfect manner.

It will thus be seen that this apparatus embodies the distinctive features to which we have referred, and in the following manner:—First, with regard to facility of feeding, we may observe that the gauges employed are so arranged and constructed as to present a constant abutment for the case to be pushed against. The case (which requires no bending) cannot be pushed over the gauge. Less care in feeding is, therefore, necessary, and a much greater speed than with ordinary presses is obtained. The press of the large size (that shown in our engraving) is fitted with two sets of gauges, for feeding front and back, so that, with two attendants, feeding front and back, so that, with two attendants, two blocks can be worked at the same time, which renders this press equal to two of the smaller size. Next, with respect to solidity of design, it will be seen that the columns tie the head and top bearings, bed, and standards, in the most compact and rigid manner. The support at each side of the eccentric prevents deflection of the eccentric shaft. The table is supported by the sliding wedge the whole of its width, and as it is capable of resisting any pressure, the whole power of the press is concentrated upon the work instead of being wasted, as in ordinary presses, by extraneous gearing, which, while lessening their power and being wasted, as in ordinary presses, by extraneous gearing, which, while lessening their power and efficiency, increase their cost. Finally, the driving gear and machinery being placed on the head of the press, renders it clear of the usual extraneous and dangerous gearing on the floor. The press is the same front and back, is extremely simple and accessible in all its details, and occurrently and accessible in the same from the sa pies less floor space than any other arming press.

#### BOBY'S HORSE RAKE.

Nour notice of the Smithfield Club Show we stated our intention of giving detail particulars of a very good horse rake, which had been invented and patented by Mr. Robert Boby, the agricultural engineer of Bury St. Edmunds. We now append the following description, premising that the rake is so arranged as that when it is full of collected material the power of the horse is emcollected material the power of the horse is employed to raise the tines and liberate the material. In our engraving, fig. 1 represents a side elevation of a horse rake constructed according to Mr. Boby's improvements. The shafts or draught irons a are connected through link bars b b with a pair of arms c made fast to the axle d of the running wheels of the machine. The times e are mounted on a transverse round bar f, carried in front of the axle d by pairs of arms g, also affixed to the axle d, but at any convenient angle to the first-mentioned pair of arms c. In order to make the shafts or draught irons g adjustable with respect to the arms g and g on the axle (with the view of setting the times g properly to their work), they are coupled arms c and g on the axle (with the view of setting the tines e properly to their work), they are coupled to the link bars b by the intervention of two pairs of clamping discs or surfaces h, seen in the plan view, fig. 2, of one of the shafts. From a transverse bar i forming part of this coupling projects rearwards an arm i, upon which is pivoted a catch lever j. Upon this catch lever rests the horizontal arm of a crank lever k, made fast to the axle d at about the middle of its length. This lever k is connected by a like k! to a lever 1 prothe axis a at about the middle of its length. This lever k is connected by a link  $k^{\dagger}$  to a lever l provided with a handle readily accessible to the attendant. So long as the rake is required to gather, the crank lever k is held in position by the pendant catch lever j, and the pull of the horse serves merely to traverse the rake over the field. When, however, a sufficient amount of material is gathered by the tines, the attendant disengages the catch lever j by means of the chains j, and the pull of the horse then causes the axle d to rock, and the bar f carrying the tines will be depressed and caused to throw up the tines into the position shown by dots, and thus clear it of the collected material. The readjustment of the rake is effected by the attendant seizing the handle of the crank lever l, and pulling it over until the catch lever l again engages with the crank lever l. Instead of the rake being thrown into action by When, however, a sufficient amount of material is lever j again engages with the crank lever k. Instead of the rake being thrown into action ky the attendant, an attachment on the running wheel or the nave of the wheel may act upon the levers k and g, and lower the tines ready for work. Wo understand that this horse rake is in use in various parts of the United Kingdom, and proves a very settificatory implement. atisfactory implement.

CAPTAIN COWPER P. COLES, R.N., C.B., has made some experiments with a composition for preserving ships' bottoms, and also with an anti-fouling composition, which have proved highly successful. We shall have a little more to say on this subject in our

#### **Obituary.**

WE have to announce the death of Sir Henry Ellis, who has held for nearly 30 years the post of Principal Librarian of the British Museum. He was born in 1777, so that he was in his 92nd year. He received his early education at Merchant Taylors' School, whence in due course he passed as a scholar to St. John's College, Oxford. He took his degree at the end of the last century, and was elected to a Fellowship. He was appointed principal librarian of the Museum in 1827, and was for many years one of the most active members of the Society of Antiquaries. In middle life, he was indefatigable as an author; among the most valuable of his publications are his "Original Letters Illustrative of English History, with Notes and Illustrations," mainly from the autograph originals in the British Museum, the State Paper Office, and other sources. We also have to announce the death of Mr. C. R.

Weld, late assistant secretary to the Royal Society from a sudden attack in the region of the heart, which happened a few days since, at his residence, New Bridge-hill, near Bath. He was in the 56th year of his age, having been born in 1813 at Windsor. He was the son of Mr. Isaac Weld, of Dublin, where he was educated, and was called to the Bar, at the Middle Temple, in 1844. In 1845 the Bar, at the Middle Temple, in 1844. In 1940 he was appointed assistant secretary and librarian to the Royal Society, and held that post for upwards of 15 years. He was known as the author, interesting the Boyal Society," pubof 15 years. He was known as the author, interalia, of "The History of the Royal Society," published in 1847; "Auvergne, Piedmont, and Savoy," in 1848; "A Vacation Tour in the United States and Canada," in 1854; "A Vacation Tour in Brittany," in 1856; "A Vacation in Ireland," in 1858; "The Pyrenees, East and West," in 1859; "The Highlands, Orcadia, and Skye," in 1860; "Sketches in India," in 1862; "A Winter in Rome," in 1865; "Florence, the new Capital of Italy," in 1867; besides which, he was the author of soveral pamphlets on subjects connected with of soveral pamphlets on subjects connected with Arctic explorations.

#### Correspondence.

GRINDING CORN.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE.'

GRINDING CORN.

SIR,—The statement on this subject, transferred to your columns from the "Agricultural Journal," only proves what barbarous means are sometimes adopted in order to perform the most simple mechanical operations. The system of nine-story millstones is a fair sample, and shows that the remote city on the Danube is much more abundantly supplied with labour and materials than with true mechanical knowledge. Your further statement that chemical science proves that the outer integuments in which the fine flour is enveloped, contains the elements required for building up the animal frame, is true, so far as chemistry is concerned, but you omit to state that, even if those integuments be ground to fine powder, they cannot be assimilated in the human stomach as they are in that of graminivorous animals, who increase in museular power and fat, when fed upon dry hay alone, a food upon which we could not exist, much less thrive. It is, therefore, utter waste to fill our stomach with ground bran, which is much more profitably employed for animal food; but, as white flour and bran have opposite qualities, the former being constipating and the latter opening, the best plan is to make use of both white and brown bread alternately, a practice that will obviate the necessity of having frequent recourse to aperient medicines.

The practice followed at the Hatcham Mills by

The practice followed at the Hatcham Mills by the Messrs. Chapman and Co., though of course protected by Royal letters patent, is nearly as bar-barous as that in use at the Hungarian mills of Pesth, for they might just as well grind up wood, parous as that in use at the Hungarian mills of Pesth, for they might just as well grind up wood, fibre, and bark, as is the custom in Sweden and Norway, when cereals are scarce. A small portion of the inner integuments of the grain, ground fine with the flour, make very good and wholesome brown bread, but the best is made with a mixture of wheat and rye ground together. In the matter of grinding corn, as exclusiveness is a main object of manufacturers of every description, a host of very use-less patents are continually being taken out, merely with the view of excluding others from following the same process, while it should always be borne in mind that all patent and advertising expenses must ultimately be paid by the consumer in some shape or other. The antagonistic patents for ventilating and dressing millstones are properly arranged they will ventilate themselves; and in regard to dressing, twenty minutes for each face is ample time for the operation by hand.

Our bread, especially from first-class bakers, is beautiful to look at, but we shall never obtain good sound bread until a certain kind of compact between the miller and baker be broken up—that is to say, the baker will not purchase flour from the miller unless it will carry a certain customary amount of water to the sack. Consequently, the miller will never purchase much new as long as he can obtain old wheat, which has been stacked some years in the rick to heat and sweat, as he calls it. The tobacco manufacturer tells the same tale, that he must make up the leaf into enormous bales in order to heat and sweat, whereas the pure leaf, merely must make up the leaf into enormous bales in order to heat and sweat, whereas the pure leaf, merely damped for cutting, makes by far the finest smoking tobacco, but he will produce nothing of the kind. New wheat, when thoroughly dry, undoubtedly makes the best bread, but the flour from new wheat will not carry nearly so much water as that from old, hence the preference of the baker for the flour of old wheat, and also the introduction of alum by both the miller and baker, in some shape or other, in order to produce a loaf that may look "beautiful for ever," with an undue proportion of water concealed in it. of water concealed in it.

of water concealed in it.

I cannot agree with the observation of the Messrs. Chapman, that millstone grit is ever found in good bread, for the wear of the stones is in the dressing, and not in the grinding operation. I forbear to trespass upon your space on this subject, more especially as I have repeatedly described the best processes in various public prints, as far back even as the year 1824.—I am, Sir, yours, &c.,

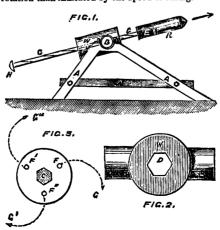

HENRY W. REVELEY.

Reading, January 18.

[As the world is ever ready to learn, and ever prone to forget the lesson taught, we think our correspondent would be doing the public a service by sending us a few more remarks on the best processes of dressing corn and converting it into food; at any rate, we shall feel obliged to him.—Ed. M. M.]

#### WAR ROCKETS.

SIR,—On reading the article on war rockets, by Mr. James Nasmyth, C.E., in your number of January 15, I came to the conclusion to give publicity to an invention I made some time ago. I am quite of Mr. Nasmyth's opinion that axial rotation for firing elongated shot is not only a desideratum, but a capital point. I however, venture to say but a cardinal point. I, however, venture to say that Mr. Nasmyth is no artillerist, otherwise he would not have invented for war purposes such a complicated and easily deteriorating machine for firing war rockets as he has. It is a desideratum in artillery to have instruments of the most simple in artillery to have instruments of the most simple and manageable construction, giving the greatest amount of force and precision obtainable. And this is not the case with that of Mr. Nasmyth, however ingenious the principle may be. We have in our artillery war rockets which rotate; they are on the principle of the "skew hole" system. I am opposed to that principle for war rockets, as the rotative force is, in a certain sense, dependent upon the atmosphere, and it is not possible to control the flight of the projectile (rocket). I object to the statement of Mr. Nasmyth that a rocket, to obtain the necessary flight and precision. must possess the ment of Mr. Nasmyth that a rocket, to obtain the necessary flight and precision, must possess the highest degree of axial rotation. Such an enormous rotation will give as a resultant an enormous deflection (perhaps normal), which is not easily corrected. Besides this, my opinion is that uniform rotation is necessary for accuracy, not that I mean a projectile must have the same number of revolutions on each point of the parabola described by it, but that the commencement of rotation must be the same for all at the moment of leaving the gun. I am but that the commencement of rotation must be the same for all at the moment of leaving the gun. I am strongly opposed to the idea of artillerists, that a gun rifled at such and such a speed gives to the projectile one rotation at such and such a distance. A projectile leaving a rifled gun gets a greater rotation than indicated by the speed of rifling.

To return, however, to my invention. I beg to enclose you rough sketches of a firing carriage,

which I believe meets every requirement for firing rockets without sticks. The sketch is to be taken only as an indication of my invention, and the rockets without sticks. The sketch is to be taken only as an indication of my invention, and the description of the modus operandi only as general. In fig. 1, A A is the carriage, B B the trunnions; C is a rod in the form of a helice, passing through the hexagonal opening D, fig. 2, and working like a piston rod through W, which is rifled like the Whitworth gun. At one end of the rod C is a hollow cylinder E, fig. 1, into which is inserted the rocket R, so as to secure aim. The rocket is held in check by springs until the combustion of the charge has generated sufficient force to pull forth the rod C, and to give, by the rotation of the rod, the desired effect to the rocket; H is a check for retaining the rod C after the projectile has left the cylinder E, while it facilitates the expulsion of the rocket. Fig. 3 represents the rear end of the cylinder or tube E, with the rod C C attached to it. F F' F' are circular holes to let out the propelling gases, and which are so constructed that those gases go in the direction of the helice C C. This screwlike propulsion helps the rotation obtained by the working of the rod C C through W.—I am, Sir, yours, &c., Delft, January 17.

### Rabal, Military, and Gunnery Items.

AT the official trials of the proposed new small arm, by the Breech-loading Riffe Competition Committee, at Woolwich, last Tuesday, one target of 2.28 was made at 1,200 yards with an Enfield Martini-Henry riffe. The riffing was a 7-groove, 1 in 22in. uniform twist, by Mr. Henry, whose bullet and lubrication were also used.

WE have to record the death of the Senior Admiral of Her Majesty's Fleet and of the Bristish Navy, Admiral Sir Lucius Curtis, K.C.B., yesterday week, at his residence, at the foot of the southern slopes of Portsdown-hill, near the village of Cosham, and within view of Portsmouth, where he first entered the service, nearly 74 years ago.

within view of Portsmouth, where he first entered the service, nearly 74 years ago.

The works on St. Catherine's Rock Fort, near Tenby, are being successfully proceeded with. During the past two months, the weather has been so stormy that considerable difficulty has been experienced in procuring and landing granite and other materials, but this is now to a great extent obviated by improved extragements.

by improved arrangements.

On Tuesday week, a handsome building was publicly opened in Ocean-street, South Shields, and dedicated as a free college for the education of seamen in navigation, and all the branches of scientific

knowledge useful in their calling. The Rev. Dr. Hooppell, of St. John's College, Cambridge, is the head master.

THE United States Secretary of War has issued an THE United States Secretary of War has issued an order directing that mammoth powder only be used in firing the 15-inch guns, the use of any other being expressly forbidden until means for checking the recoil are applied to all carriages. It is ordered that no charge greater than 501b. of mammoth powder be used without instructions from the Ordnance Office. The Chassis rails are to be well searched in all firing

ordnance Office. The Chassis rails are to be well sanded in all firing.

A HANDSOMELY-FITTED steam launch, for the use of Admiral Hobart Pasha, on the Bosphorus, has just been shipped to Constantinople, by Yarrow and Hedley, the builders. The boat is 40ft. in length, cift. beam, and has a draught of 2ft. Sin. She is fitted with engines of 7 (nominal) horse power, capable of working up to 20. A cabin extends from end to end of the launch, divided amidships by a movable partition—the forward part possessing ample sleeping, &c., accommodation for three persons; the after part being allotted to the machinery. The boat is elegant, and commodious for river or harbour work. She is shipped all complete, so that on arrival at her destination, she has merely to be lowered over the ship's side, get up steam, and assume her full duties. duties

the ship's side, get up steam, and assume her full duties.

The Prussian "Military Gazette" says that the German military organization is now complete and that "a million of soldiers, can at any moment be placed under arms by a single telegram form Berlin." The Prussian troops, it adds, consists of 325 battalions of infantry, 268 squadrons of cavalry, 11 regiments of artillery, with 1,146 guns, and 12 battalions of engineers, making 410,000 soldiers in all. To these, says the "Pall Mall Gazette," should be added the Federal contingents, which are as follows:—Saxony, 29 battalions, 24 squadrons, 96 batteries, and 6 guns; Brunswick, 3 battalions, 4 squadrons, and 6 guns; Mecklenburg-Strelitz, 1 battalion; and Hesse Darmstadt, 10 battalions, 8 squadrons, 24 guns, and 1 battalion of engineers; total, 53,000 men. But, says the "Military Gazette," this force of 463,000 men only represents the standing army of North Germany. "In cases of emergency, Prussia can also command the services of the troops of Baden, Wurtemburg, and Bavaria, and immediately order a levy of her reserve, consisting of 120 battalions of infantry, 76 squadrons of cavalry, 240 guns, and 12 battalions of engineers; or an army of 143,000 men. An additional force of 200,000 men is at her disposal for the occupation of towns and garrisons. The above numbers do not include the officers, military train, military labourers, nor special corps of any kind." train, military labourers, nor special corps of any

tran, mintary labourers, nor special corps of any kind."

An article on the new firearms, published by the "Journal Official," says:—"The result of a comparative trial which took place in the School of Musketry, at Spandau, in Prussia, amongst the breech-loaders adopted by the different armies, were, according to the official report, the following:—The Prussian needle gun can fire 12 shots a minute, the Chassepot 11, the Snider 10, the Remington (Denmark) 14, the Peabody (Switzerland) 13, the Wonzi (Austria) 10, the Werndi (same State) 12, and the Winchester repeating rifle (United States) 19.

The breakwater constructed some years ago in St. Catherine's Bay, Jersey, for the purpose of a naval station, but which has remained wholly unused ever since, has just been offered by the Government to the island authorities, on condition that they will add the necessary works to convert it to a harbour. The offer is opportune, because the States contemplate providing a deep-water harbour, the absence of which is specially inconvenient to the mail packets, and a hindrance to passenger traffic. It is proposed,

which is specially inconvenient to the mair packets, and a hindrance to passenger traffic. It is proposed, if a deep-water harbour can be secured cheaply, either at St. Catherine's or elsewhere, to connect it with St. Helier's by a short line of railway, or, on the other hand, by a road tramway.

#### Mistellanea.

WE are glad to observe that the efforts made towards the art education of the working men in all countries multiply daily. The municipal council of Brussels, aided by a vote of the Belgian Chamber, has reorganized its industrial museum, and opened a school for the artistic education of workmen.

A TRIEGRAM from San Francisco states that during the last half of 1868 that port exported 150,000 tons of wheat and 240,000 barrels of flour, and in the aggregate to an export of 184,000 tons

equal in the aggregate to an export of 184,000 tons of wheat. The amount of wheat still on hand is estimated at 180,000 tons in California and 80,000

esumated at 180,000 tons in California and 80,000 tons in Oregon.

DURING 1868 the total number of immigrants landed at New York was 212,989, a decrease of 29,772 as compared with the previous year. There were 4,861 arrivals of vessels at New York from foreign ports in 1868, as compared with 4,976 arrivals during 1867. Of these arrivals in 1868, the American 67. Of these arrivals in 1868, the American ssels numbered 2,395, the British 2,082, the North

German 379, and the French 29
The Post-office in the Rue Jean-Jacques-Rousseau ordinarily receives about 20,000 letters each evening

from 5 to 6 o'clock, but on the eve of New Year's Day not less than 200,000 passed through its offices between those hours. The administration distri-

between those hours. The administration distributed 3,000,000 of visiting cards this season, and, notwithstanding the assertion that the fashion is dying out, there is an increase for the present year.

THE election of a foreign member of the Paris Academy of Beaux Arts, in the place of the late composer Rossini, has fallen on Signor J. Dupre, sculptor, of Florence, Signor Dupre exhibited in the Champ de Mars, in 1867—"Piety" a group in marble; "The Infant Bacchus," a statuette; and "The Triumph of the Cross," bas-relief in plaster; and was awarded by the jury one of the grand prizes. prizes

and was awarded by the jury one of the grand prizes.

In a communication to Paris, M. de Lesseps states that a small schooner, "La Levrette," has recently passed through the Suez Canal, and that six vessels belonging to the Egyptian fleet are about to pass from one sea to the other. It now may be safely said that this canal is opened for vessels of small tonnage; and in six months' time ships of from 2,000 to 3,000 tons burden will be able to make use of the Suez Canal.

The Parliamentary deposit on the proposed new line to Brighton has not been paid, and the project has thus, for the present, been abandoned. It appears that as many as five petitions against the bill, on the ground of non-compliance with standing orders, had been lodged in the Private Bill office of the House of Commons—one by the Brighton Company, one by the South-Western Company, and three others nominally by private individuals.

The progress of the St. Marylebone Bank for Savings, during the past year, has been of a satisfactory description, as appears from the following statement just issued:—Received from 1,726 new and 16,337 old depositors, £83,039 0s. 7d.; repaid to 8,248 depositors in part and 1,400 in full, £78,100 16s. 3d. Increase, open accounts, 326; money, £4,938 4s. 4d. Number of accounts remaining open, 32,973; amount

15,337 old depositors, £83,039 0s. 7d.; repaid to \$,248 depositors in part and 1,400 in full, £78,100 16s. 3d. Increase, open accounts, 326; money, £4,938 4s. 4d. Number of accounts remaining open, 32,973; amount due, £313,633 12s. 7d.

The number of visitors to the South Kensington Museum during the week ending January 16, 1869, was—on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 16,576; Meyrick and other galleries, 3,362; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 2,277; Meyrick and other galleries, 317; total—22,532. Average of corresponding week in former years, 9,899. Total from opening of Museum—8,073,624. A CLERGYMAN, whose name is stated to be Mr. Wild, has been lecturing in Canada, taking for his subject "What the world is coming to." He announces these among other things looming in the distance:—Coral insects will fill up the Pacific with solid habitable land; eventually the globe will be all land, or at least there will be no more sea; there is also to be perpetually equal day and night of twelve hours each all over the globe; there is to be only one language spoken throughout the world, and wither frequence will be English"

twelve hours each all over the globe; there is to be only one language spoken throughout the world, and "that, of course, will be English."

The other day, while engaged in digging the foundations of the new Home for Sailors' Orphans between Church-row and High-street, Hampstead, a working man came upon a leaden coin, about 2ft. below the surface, in a bed of loam and clay. It is about 1½in. in diameter, and on inspection it turns out to be a "bull" of Pope Innocent IV., one of the well-known family of Fiesco, who sat in the chair of St. Peter from A.D. 1243 to 1255. The "bull" bears on the reverse the figures of St. Peter and St. Paul, and is in a tolerable state of preservation; and we understand that it is likely to be secured for the British Mussum. the British Museum.

the British Museum.

THE Society for the Encouragement of Mandfactures and Mechanical Industry in the Netherlands proposes to arrange an international exhibition of articles for daily household use, at Utrecht, in the months of August and September, 1869. The principal object of this exhibition is to bring to the knowledge of the workman such articles of household use, furniture, dress, food, work, and instruction of different countries, as at a low price, combine use, lumiture, gress, 100d, work, and instruction of different countries, as, at a low price, combine usefulness and solidity, so that he may be enabled, by judicious economy, to improve his condition. Articles of luxury, as well as of elegancy, strictly so called, are excluded.

called, are excluded.

THE gold diggings in the Strath of Kildonan and the Seisgill Burn are attracting large numbers of treasure-seekers. No nuggets of any great size have been got, but a number of people have succeeded in getting quantities estimated in some instances as high as to pay them from 5s. to 30s. for their day's work. The gold is got in small particles in the alluvial soil washed down from the mountains by the river; and in consequence of the swollen state of the streams at present this is the most unfavourable system for prosecuting the search. It may, of the streams at present this is the most unavour-able system for prosecuting the search. It may, and doubtless will, happen that the net gains of the parties engaged will dwindle down considerably when they come to be tested; but at present the belief is strong in the district that the gold washing

and placed under an experienced mauager, every precaution being taken for the exercise of rigid economy. The result appears to be that there is already a steady outturn of coal, and that attention is being paid at Singapore and elsewhere to its valuable peculiarities for steam and gas purposes. At the same time, the working even on its present scale has been brought to yield a surplus over expenses. The latest accounts confirm the impression that the quantity available is practically inexhaustible.

scale has been brought to yield a surplus over expenses. The latest accounts confirm the impression that the quantity available is practically inexhaustible.

At a general meeting of the Royal Horticultural Society, held on Tuesday last, Mr. James Bateman, F.R.S., vice-president, in the chair, the following candidates were elected fellows of the society, viz:—His Serene Highhess the Prince Teck, His Highness the Prince Hassan Pacha, Mrs. Wm. Butt, Henry Cannell, Hon. Richard Walter Chetwynd, Lord Alfred Spencer Churchill, Arnold de Baruchsen, Mrs. Henry Fenwick, Rev. Frederick Leicester Viscount Milton, M.P., W. R. Morris, George Lake Russell, Rev. Sanderson Tennant, Miss Thompson, Frederick J. Toulmin, Hugh F. Underwood, Henry Jones Winsett. &c. This was the first of the society's scientific meetings, and a very fine collection of plants and fruits was brought together. The total quantity of coal imported into France, in the first nine months of 1868, was 4,748,213 tons, as compared with 4,874,667 tons in the corresponding period of 1867, and 4,846,610 tons in the corresponding period of 1867, and 4,846,610 tons in the corresponding period of 1867, and 4,846,610 tons in the corresponding period in the france to September 30, 1868, 1,299,301 tons came from the United Kingdom, 2,582,887 tons from Belgium, and 860,319 tons from the Zollverein. In the first nine months of 1867 the corresponding receipts stood thus:—From the Zollverein, 851,901 tons.

A census of Chicago, taken on the 1st of October, 1868, shows its population to be 252,054, an increase of 51,636 since the census taken two years before. Chicago has just completed, ready for opening to the public on New Year's Day, a tunnel under the river which flows through the city. The contract price of this work was 328,500 dollars. The length is about 1,605ft.; of the retaining walls of the open approach on the west side about 320ft., and 275ft. on the east side. The length of the main archway, or covered way, is 932ft. There are three archways leading through

### Patents for Inbentions. ABRIDGED SPECIFICATIONS OF

**PATENTS** THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

when they come to be tested; but at present the belief is strong in the district that the gold washing will pay.

Advices from Labuan give at length satisfactory prospects of the working of the coal mines at that island. After the break up of the China Steam and Labuan Coal Company, the property was bought for a small sum by a few meu of business in Scotland

2125 A. KANE, Dundee. Tobacco-pipe apparatus. Dated July 3, 1868.

2125 A. KANE, Dundee, Tobacco-pipe apparatus. Dated July 3, 1868.

The patentee makes the mould of the pipe in halves, and holds them in a cramp. The two creeks of the mould are pressed together by a screw. To a lever a stopper or piston is attached, so that when the lever is pressed down-wards, the stopper or piston enters the part of the mould where the head or bowl of the pipe is formed, and forces the clay which has been placed therein. The bore or tube in the "staple" of the pipe is formed by a wire which is fixed to a guide block and actuated by a rod connected to the end of the lever.—Patent abandoned.

2126 J. H. JOHNSON, Lincoln's Inn-fields. Paper pulp. (A communication). Dated July 3, 1868.

The patentee proposes to apply in the vat containing the pulp, and in proximity to the cylinder ordinarily employed, an additional apparatus to feed the pulp between the teeth or blades of the cylinder and those of the block in lieu of causing the cylinder itself to agitate, and thus effect the supply of the pulp as well as effect it trituration, as in the ordinary manner. The feed apparatus may consist of a drum provided with pallets, or a pump or other apparatus, suitable for the purpose intended. The cylinder being elevated above the pump is not required to overcome the resistance to which it is ordinarily subjected, and as the power expended in feeding is but small, a considerable saving in motive power is effected.—Patent completed.

saving in motive power is effected.—Patent completed.
2127 G. BENNETT and J. WOODGOCK, Manchester. Railway communication. Dated July 3, 1868.
A revolving fan is employed to create a current of air, the fan being worked from the axle of the engine or carriage, the air may be applied to sound a whistle or other alarm outside the carriage from which the communication is desired.—Patent completed.

13 desired.—Faten completed.

2128 J. and G. M. WARD, Gorton, Lancaster. Locomotive engines. Dated July 3, 1868.

This invention consists in the employment of an air valve in communication with each steam chest for supplying air to the chests and cylinders when the pistons and slide valves are working with the steam shut off.—Patent abundance. abandoned.

J. B. Brown, Northumberland. Calcining ores

stide valves are working with the steam shut on,—Fatent abandoned.

2129 J. B. Brown, Northumberland. Calcining ores. Dated July 3, 1868.

The ordinary way of heating a close furnace is by passing the flame between the two arches at the top of the furnace and then once or oftener under the tiles which form the bottom of the furnace. This invention consists in converting the space between the two arches into an open furnace to which the ore or mineral is first supplied; the ore afterwards descends into the space below the lower arch, which space forms the close furnace. The invention is carried out by levelling the top of the lower arch so as to form an upper bed to receive the ore or mineral; this lower arch is strengthened, if necessary, and the distance between the two arches must be sufficient to allow the ore to be worked on the upper bed or top of the lower and,. The flame passes first over the ore on the upper and open bed and then under the ordinary lower bed to the chimney. By means of this the patentee is able to get rid of any excess of sulphur on the upper bed before adding common salt or other chloride to the ore in the lower bed or close furnace; the gases from the two beds are kept separate and distinct, those from the lower bed being collected and condensed, if necessary, should it be desired that the ore on the upper and open bed be subjected to a lower degree of heat than when in the lower bed on lose furnace, this can be effected by causing the flame from the fuel to pass under the tiles of the lower bed, then between the arch of the lower bed and then ascending to pass over the ore on the floor of the lower bed, then between the arch of the lower bed and a set of tiles made to form the floor of the hour bed, then between the arch of the lower bed and then finally over the ore on the upper bed, and then finally over the ore on the upper bed to the chimney.—Patent completed.

2100 W. E. Newron, Chancery-lane. Automatic toys. (A communication). Dated July 3, 1868.

and then finally over the ore on the upper bed to the chimney.—Patent completed.

2130 W. E. Newton, Chancery-lane. Automatic toys.
(A communication). Dated July 3, 1868.

The automaton toy which forms the subject of the present invention is constructed to represent a human figure or mechanical man capable of driving a carriage before him, the legs of the fluure being made to move as if walking. The patentee claims, first, the construction of the leg of a toy adapted to imitate the movements of the natural leg, the general arrangement and construction of parts, and particularly the attachment of a bar to the foot at a point in advance of the point of attachment of the foot bar. Second, the frame and hip plates to which the legs are attached, and by means of which the legs are connected with the body of the toy, as described. Third, the construction of the legs and feet, or movable parts of the toy, whereby, when the toy is moved over the foor, the parts are caused to imitate the movements of the corresponding parts of the natural limb which it is designed to represent.—Patent completed.

2131 M. HENRY, Fleet-street. Provision cases. (A com-

sponding parts of the natural limb which it is designed to represent.—Patent completed.

2131 M. Henny, Fleet-street. Provision cases. (A communication). Dated July 3, 1868.

The case is made of tin, tin plate, or other like metal, on which a varnish or coating is applied and fixed by heat or otherwise, thereby preserving the metal from oxidation, and the contents from discoloration and injury. Various varnishes or coatings may be used, but the one preferred consists of gum copal, linseed oil, and essence or spirit of turpentine. In the bottom of the box or receptacle is an oritice or hole through which the jam or other provision is inserted, and when the receptacle is filled, the hole is closed by a cap or stopper which may be provided beforehand, or with solder or cement, so as to fasten it instantly by heating it over a soldering iron. The cover overlaps the rim, and its flange or lip drops over a neck or recessed part of the receptacle, and a ring or guard is placed round it of sufficient length to facilitate its removal when the box is to be opened. The bottom of the box is made convex towards the outside or under side. When the contents of the receptacle are poured in in a hot state, they shrink as they cool, producing a vacuum or partial vacuum inside the receptacle, so that the bottom yields under the external pressure, or assumes a flat or a concave form, being pressed inward by the atmospheric pressure against the contents, which it packs tightly.—Patent completed.

2132 J. A. MULLER, Amsterdam. Gas meters. Dated July 4, 1868. This relates to an improved meter for regulating and

This relates to an improved meter for regulating and registering the flow of liquids and gases, and the said meter consists of a hollow cylindrical chamber in which works a water and air-tight piston or disphragm, the cylinder having a cover at each end, provided with a stuffing box, through which a tappet works, the tappet in

the top cover being operated upon by the ascent of the piston or disphragm, and the tappet in the bottom cover by the descent thereof. Both at the top and bottom of the cylinder is a port for the admission of the liquid or gas, and opposite to these ports are other ports for the exit of the liquid or gas; valves or slides actuated by levers in communication with the tappets operated by the piston or disphragm are worked over these parts in their respective valve cases in such manner that the liquid or gas is admitted alternately to the top and bottom of the cylinder, thus accurately regulating the supply thereof. By means of cog wheels and pawl and ratchet, or other equivalent gear, in connection with the tappets operated by the piston or disphragm, the supply of liquid or gas can also be accurately registered on an ordinary indicator.—Patent completed.

2133 J. Head, Middlesborough. Furnace grate.

2133 J. Hrad, Middlesborough. Furnace grates. Dated July 4, 1868.

This invention has reference to that class of grates known as stop grates, that is, such as have the grate bars arranged one above the other, upon an inclined plane. By this invention each bar is supported upon two or more shanks or levers, which can be projected downwards at right angles to the bar. These levers or shanks, if of wrought iron, should be swaged down somewhat smaller at the upper end, and inserted into holes cast or otherwise made in the bar, which should be of cast iron. They can be further secured by wedging or tiveting, if desired, or they may be cast upon the bar, as hereafter described. A few inches below the bar a hole is made in the shank, through which a bolt or pin is inserted, attaching it to the frame, and which carries the weight of the bar, leaving it free to turn upon the pin or bolt in an arc of a circle. A few inches below this hole in the shank another hole is provided, containing another bolt, which attaches the extremities of all the shanks. The bars are cast with shanks and projecting pins or centres. The upper pins rest in notches in the frame for easy removal, and the connecting bars hook on to the lower pins. The bars are cast with shanks and projecting pins or centres. The upper pins rest in notches in the frame for easy removal, and the connecting bars hook on to the lower pins. The bars are supported upon a carriage or bogle, formed of a piece of iron and supported upon two wheels, which run upon light rails near the floor of the ashpit. The wheels are placed so that when the grate is at its proper inclination, they are nearly in the line of its centre of gravity. The frame can be continued outside the furnace, and be connected by a long bolt running through a wooden strut and raise or lower or draw in and out, or otherwise. The attendant can take hold of this wooden strut and raise or lower or draw in and out, or otherwise. The attendant can take hold of this wooden strut and raise or lower or draw in an 2133 J. HEAD, Middlesborough. Furnace grates. Dated July 4, 1868.

This invention has reference to that class of grates

backwards upon the wheels.—Patent completed.
2134 A. Fayer, Manchester. Concentrating sugar. Dated
July 4, 1868.

The patentee passes the gases or products of combustion,
either with or without an admixture of air, between a
series of spiral blades or volutes symmetrically arranged
and revolving round a common centre. The external
edges of these blades, in their lowest position, are immersed in the solution to be operated upon, and by their
revolution, the solution flowing over their surfaces towards
the common centre preserves the surfaces in a moist
state. The heated gases passing over these moistened
surfaces effect the concentration desired.—Patent completed.

state. The nested gases passing over these indisates surfaces effect the concentration desired.—Patent completed.

2135 A. Albini, Genoa. Compasse. Dated July 4, 1863. Under the usual compass card the patentee fixes a metallic ring divided on its under side into the same number of points as and corresponding to those of the compass card. At each division the ring is engraved with one or more letters, figures, or conventional signs, to indicate the compass points, and capable of answering as printing types. The compass card fitted with the ring is suspended in the usual way upon a central pointed support fixed upon a metallic frame containing clockwork arrangement. On the face of one of the frame plates is a clock dial to indicate the time, and on the opposite frame plate is a piston or roid geared to the clockwork, and made by its action to rise and fall at fixed intervals. The upper part of the piston or sliding rod is bent at right angles, so as to project above the card ring. On the bent part of the sliding rod a small metallic point is fixed vertically, the point being fitted with a spiral spring. Fixed on the front frame plate, and at the back of the sliding rod, is a small horizontal elastic cushion, and in the same line, is fixed as small horizontal plate, carrying in its centre a small well filled with a suitable coloured liquid, and a little above the plate a narrow silk ribbon or other material is fixed, one end dipping in the well and the other end being fixed to a metallic support at the further end of the elastic cushion, the ribbon being supported a little above the surface of the said cushion. The apparatus is suspended on gimbals, to allow for the motion of the ship.—Patent completed.

2138 A. M'NIEL and W. Weerlann, Exeter. Salts of ammonia. Dated July 4, 1868.

to allow for the motion of the ship.—Patent completed.
2186 A. M'NIEL and W. WHEATON, Exeter. Salts of ammonia. Dated July 4, 1868.

The patentees take the ammoniacal liquor as it comes from the gas works, and add thereto gypsum or sulphate of lime (by preference reduced to a coarse powder) in the proportion of, say, 100lb. or 200lb. to 100 gallons of gas liquor, and they allow the gypsum to remain in the liquor for two or three weeks. The sulphate of ammonia thus formed will be found dissolved in the water, which, when properly saturated, may be drawn off and evaporated, and the dry substance thus obtained in a state of powder will be found to form an excellent manure.—Patent abandoned.

appears in nature or is artificially produced) is at first init mately mixed with a suitable hydrocarbon, such as gas tar, resin, petroleum, or any other analogous substance, in sufficient quantity to produce with it a stiff paste. This paste, after having been made into small balls or other suitable shapes, is dried in the air or in a drying oven, and then charged into a strong tube or retort, which is to be lined with a plumbago coating, and heat applied to it. This tube or retort must be of sufficient strength to stand a pressure of 25lb to 30lb. to the inch while exposed to a red heat, and be so arranged that by means of a safety tube or valve, the necessary amount of hydrocarbon gas can be introduced into the retort among the heated mixture, and the pressure of from 20lb, to 30lb, to the line maintained therein. To accomplish this, the hydrocarbon gas is evaporated by gentle heat from liquid hydrocarbon, and pumped by a force pump into the retort or tube, and as the gas is consumed, the supply is maintained at the requisite pressure by the pump.—Patent completed.

2138 R. Needham, Dukinfield, Chester. Feed scater appears in nature or is artificially produced) is at first inti

as the gas is consumed, the supply is maintained at the requisite pressure by the pump.—Patent completed.

2138 R. Needham, Dukinfield, Chester. Feed scater keater. Dated July 4, 1868.

This consists of two chambers communicating with one another by means of a number of tubes. These chambers may be made of any suitable shape, but the patentee prefers to give them a circular form, so that the whole forms a vessel of a cylindrical shape, having a chamber at each end, and a number of tubes reaching from one to the other. These chambers are provided with hollow trunnions, and the vessel is arranged so as to rotate and expose each portion of the surface equally to the heat. The action of the apparatus is as follows:—The water being forced in, passes through the trunnions into the chamber, and thence along the pipes in a number of separate streams to the other chamber, being heated in its passage; it then passes through the other trunnions and pipes into the boilers. The vessel may be arranged so as to rotate either horizontally or vertically.—Patent abandened.

2139 T. G. MESSENGER. Loughborough. Horticultural

The vessel may be arranged so as to rotate either horizontally or vertically.—Patent abandened.

2139 T. G. MESSENGER. Loughborough. Horticultural buildings. Dated July 4, 1868.

This invention consists in part in the construction and arrangement of a number of glazed lights of equal or unequal widths fixed on one or more sides of a conservatory or other building used for horticultural or other similar purposes, such lights being hung in such manner that the whole or any number of them, on the same side, may be opened at one and the same time any required distance. The machinery or apparatus employed consists of screws and toothed wheels and worms, or their equivalent, for the purpose of opening and closing the lights before mentioned. The wheels or worms employed, or their equivalent, by acting upon a screw and travelling nut, move a rod to which are fixed arms to move the lights, and the worm and toothed wheel are fixed upon a rod to which is attached a groove wheel, in the groove of which runs an endless band or chain worked by a second wheel, and a handle fixed in any convenient part of the building to be ventilated, or the motion may be given by a rod or countershaft, to which is attached a worm and handle to act upon the worms and upon the wheels and screws and arms, or other equivalent before mentioned, for moving the light or lights required to be opened or closed; or motion may be given equivatent cetore menuoned, for moving the light or lights required to be opened or closed; or motion may be given direct, by means of a handle fixed in the place of the grooved wheel before mentioned, or otherwise, according to the requirements of the situation.—Patent completed.

to the requirements of the situation.—Patent completed.
2140 A. M. CLARK, Chancery-lane. Boot fasteners. (A communication). Dated July 4, 1868.
This consists in the employment of hooked studs to enable a boot or other article to be fastened much more readily than by other means, and further possess great strength. The hooks are disposed along each side of the opening in the boot, bag, or other article to which they are applied.—Patent completed.

2141 G. SLATER, Lamb's-passage, London. Folding cloth.

2141 G. SLATER, Lamb's-passage, London. Folding cloth. Dated July 4, 1868.

The patentee employs smooth or plain cylindrical pressing rollers, or a single plain roller arranged in combination with a vibrating or reciprocating folding bar or plate, the rollers being heated by gas or otherwise. A folding bar is caused to vibrate over the surface of the roller or table, by means of a crank or eccentric geared in connection with the roller, and at each vibration it forms a plait or fold, which is instantly carried forward and compressed between the rollers. The machine may be provided with a driving pulley, and driven by a steam engine, or may be operated by hand or other power.—Patent abandoned.

operated by hand or other power.—Patent abandoned.

2142 J. KILNER, F. H. ODLEE, and E. BUENS, Manchester

Cork drawer. Dated July 6, 1868.

This consists of a peculiarly shaped instrument, with an
angular or bent point, which is passed between the cork
and the neck of the bottle, so as to bring the angular or
bent point of the instrument below the cork, when by
turning the instrument half a revolution, the angular or
bent point is placed across the cork, and by withdrawing
the instrument, the angular or bent point brings the cork
along with it.—Patent abandoned.

2143 P. LENSEN BRIVEON. Seeing machines. (A commun-

se a piston or rod geared to the clockwork, and made by its action to rise and fall at fixed intervals. The upper part of the piston or sliding rod is bent at right angles, so as to project above the card ring. On the bent part of the sliding rod a small metallic point is fixed vertically, the point being fitted with a spiral spring. Fixed on the front frame plate, and at the back of the sliding rod, is a small horizontal elastic cushion situated a little below the ring of the compass card when suspended. A little below the ring of the compass card when suspended. A little below the ring of the compass card when suspended. A little below the plate with a suitable coloured liquid, and a little above the plate a metallic support at the further end of the elastic cushion, the ribbon being supported a little above the surface of the said cushion. The apparatus is suspended on gimbals, to allow for the motion of the ship.—Patent completed.

1336 A. M'NIEL and W. Wielator, Exeter. Sails of ammonia. Dated July 4, 1868.

The patent abandoned.

1367 A. M'NIEL and W. Wielator, Exeter. Sails of ammonia. Dated July 4, 1868.

The patent abandoned. A little below the ring of the compasses of the said cushion. The apparatus is suspended on gimbals, to allow for the motion of the ship.—Patent completed.

1368 A. M'NIEL and W. Wielator, Exeter. Sails of ammonia. Dated July 4, 1868.

The patent abandoned.

1369 A. M'NIEL and the other end being fixed to a metallic support as the torial patent of the said cushion. The apparatus is suspended on gimbals, to allow for the motion of the ship.—Patent completed.

1370 A. M'NIEL and W. Wielator, Exeter. Sails of ammonia the proportion of, say, 100lb. or 200lb. to 100 gallons of gas liquor, and they allow the grpsum to remain in the liquor for two or three weeks. The sulphate of ammonia thus formed will be found dissolved in the water, which, some part of the spot hook. The support patent of the spot hook. The support patent of the spot hook, by which means a better struck and the dry su

ing the spring or the tension at each time. The stitch regulator consists in a lever, the fulcrum of which is fixed on the clothplate. The clothplate has a graduated index on it, one end being made to press the feed-bar more or less away from the feed eccentric, which gives lateral motion, and regulates the length of the stitch—Patent completed.

completed.

2144 A. FRYER, Manchester. Concentrating sugar. Dated July 6, 1868.

These improvements refer in part to improvements in the apparatus described in the specification of letters patent, dated February 14, 1865 (No. 418). The curved blades are placed as close togother as can be done without interfering with the flow of the liquor or other solution over their surfaces, so as to divide the air, thus bringing every portion of it into more intimate contact with the solution to be evaporated or concentrated, and thereby more perfectly exhausting the whole of the heat contained in the air. The curved blades are placed at from five eighths to one-eighth of an inch apart, according to the nature and degree of saturation of the solution to be acted upon.—Patent completed.

2145 G. DAVIES, Lincoln's-inn. Locomotive engines. (A

acted upon.—Patent completed.

2145 G. DAVIES, Lincoln's-inn. Locomotive engines. (A communication). Dated July 6, 1868.

This consists in the direct application of locomotives of one or more rotary engines, giving motion to one or more pairs of horizontal wheels, which, pressing against the vertical faces of a central rail, enable the train to travel over the heaviest gradients. The machinery may be composed of a rotary steam engine, two shafts, and two horizontal wheels, and the frame screws and springs to produce any required amount of pressure on the central rail. The apparatus can be placed either on the locomotive or on its tender.—Patent completed.

produce any required amount of pressure on the central rail. The apparatus can be placed either on the locomotive or on its tender.—Patent completed.

2146 E. H. WALDENSTROM, Salford. Ricet machinery. Dated July 6, 1868.

This invention relates to the machinery employed in the manufacture of rivets, small bolts, screw blanks, and articles of a similar description, wherein the rivets or other articles are formed from a coil or a continuous length of wire, or from rods of metal, the improved arrangement of mechanism being as follows:—The metallic rod or the coil of wire from which the articles are to be formed, is supplied to the machine, either heated or not, as may be advisable, and is fed into the machine by a pair of gripping jaws which have an intermittent to-and-fro motion derived from the main slide or the slide carrying the main die, a second pair of jaws being employed to hold the rod during the backward motion of the jaws first named. The feeding jaws are fitted to a carriage mounted in slides, and is moved to-and-fro at intervals by a bar connected to the main slide, and the upper jaw is hinged to one end of a lever, the other end of the lever being acted upon by a bowl stud or projection carried by the bar when the jaws are required to grip the rod. The holding jaws consist of one fixed and one movable jaw, which is pressed towards the fixed jaw by a spring or other appliance, in order to hold the rod, and is moved therefrem to allow the rod to be fed to the cutting dies by means of a lever acted upon by the back stroke of the die and slide a regulated length of the rod is fed into a tube or ferrule in the heading and shearing block, and a sliding motion at right angles to the rod being imparted to the block, a length of wire sufficient to form a rivet is severed from the rod, the block and the surface against which it slides being fitted with shearing dies or plates. This movement brings the severed blanks opposite to the aperture the blank is thrust or injector which enters the februle in the sheari

Patent completed.

2147 J. H. Whitehead. Numnahs or saddle pads and blankets. Dated July 6, 1868.

Wool or other fibre is felted on to a coarse fabric of woven horse hair. The wool employed is coarse yellow or grey wool, or noils from the combing of long wool. An endices apron carries the ball accumulated on it into a roller hardener. As it passes into the hardener there is laid on the surface of the accumulated ball a strong openwork fabric; the whole passes together through the hardener, and the fibres of the ball become locked through the meshes of the fabric. Thus the ball and the fabric become sufficiently combined to be fulled together. The fulling operation is conducted in the usual manner, and the felting of the ball completed, the openwork fabric at the same time becomes so firmly held that it cannot be separated.—Patent completed.

2148 G. DANIES. Lincoln's Inn. Dyeing. (A communi-

at the same time becomes so irmly held that it cannot be separated.—Patent completed.

2148 G. Davies, Lincoln's Inn. Dyeing. (A communication). Dated July 7, 1868.

The unspun fibres are nordanted in the usual manner. Supposing that they are intended to be violet, they are mordanted by the ordinary process in iron mordant. The mordanting being effected, and the fibres having been well dunged, a sufficient quantity of water is added, containing such an amount of extract of madder as is found necessary. If the extract employed be acid, or if the water used be too pure, it is to be neutralized by adding a small quantity of chalk—for example, about one quarter to five per cent. The quantities of the extract or of the chalk cannot be precisely mentioned, because the commercial extract is of so variable a quality, in relation to its price, concentration, purity, and neutrality, that it is necessary to make a trial of each quantity obtained of this matter in order to obtain its strength and state of neutralization. The bath of dye being prepared, the mordanted and dunged fibres are introduced therein and dyed in the usual manner, and the inventors state that the dyeing is effected quicker than with the other derivations of madder, or with madder itself, and that the addition of glycerine to the madder or extract accelerates the dyeing still more. If there is no great hurry, fuel can be economized by dyeing at a less heat, but for a longer time. In practice, it is found advisable to dye in about an hour and a-half to two hours, at a boiling heat. When the dyeing in extract of madder is finished, there are several methods

of brightening the colour, og it may be washed with soap, as is usually done in dye works with madder violet or derivatives of madder. The fibres are to be submitted to the same treatment which a calico printer employs with madder violet calicoes, that is to say, soaped either with or without previous washing, and submitted or not to the action of chloride of lime (very weak and cold). Hitherto, in dyeing fibres, threads, or fabrics composed of vegetable and animal matters, it is difficult to impart to the vegetable fibres a solid and as beautiful a dye as to the animal fibres, but by dyeing the vegetable fibres in madder colours the patentee states that they, by means of spinning or weax-ng, mix these fibres with those of animal origin, and then proceed to dye the whole by the artificial colouring matters. Wools and silks are dyed thereby by reason of their natural aptitude, and the vegetable (previously dyed with madder) mixed therewith will take the dye in the sauge bath and at the same time their supplement of the artificial colouring matter. The vegetable fibres will not be of so pure a tint as the animal fibres, owing to the presence of the madder colours but, nevertheless, the mixture of the fibres will produce a good effect, and threads or fabrics thus produced will have the great advantage of possessing a colour and solidity hitherto unknown. In this case, for violet, it is necessary to use iron mordant, and for red or rose colour a mordant of alumina, and in the latter case, to give the supplementary dyeing in "fuchsine," or "geranocine," "coralline," or other artificial red colouring matter.—Patent completed.

2149 J. Thouson, Peckham. Chimney tops. Dated geranocine," "corall.

2149 J. Thomson, Peckham. Chimney tops.
uly 7, 1888.
This relates to chimney tops.

July 7, 1888.

This relates to chimney tops which prevent all down draught. For this purpose the upper end of the chimney top is closed, and a number of apertures formed in the sidea.—Patent shandoned.

drught. For this purpose the upper end of the chimney top is closed, and a number of apertures formed in the sides.—Patent abandoned.

2150 G. R. WILSON, Birmingham. Stereotype plates. Dated July 7, 1863.

This consists chiefly in the novel modes or processes employed to produce the impressions nor upon the indiarubber or other material. The impressions are produced either upon the shiehed vulcanized sheets or in the soft compound of which such sheets are formed, the curing or vulcanizing being in the latter case afterwards effected by the usual means. The rubber or other material and the matrix are clamped together and subjected to heat. After cooling, the vulcanized plate is removed from the matrix and is ready for use. According to one method of practising this invention, the patentee takes a sheet of hard prepared rubber, vulcanized guita-percha, or a sheet of the two substances combined, and soften the same by placing upon it a heated metal plate. The matrix or mould from which the stereotype is formed is then placed upon the softened rubber or other substance. Behind the matrix another plate of iron or other metal is placed. These two plates, with the rudder and matrix between them, are clamped or bound together, and allowed to remain so till they are cold. By this means an exact and perfect copy of the matrix is obtained upon the surface of the vulcanized plate. The metal plates may then be unfastened and the stereotype removed from the matrix is taken in the soft prepared rubber or guita-percha compound before it is vulcanized, the vulcanization being effected while in contact with the matrix, instead of using the sheets of flished "vulcanite." This soft compound is by means of calender rolls or other pressing mechanism spread in sheets or plates of the desired thickness, and is then placed upon the matrix. The rubber or other material and matrix together are then secured between two metal plates and placed in a heater or vulcanizer and heated. They are then subjected from two to three hours to a temper

wo metal piates and placed in a heater or vulcanizer and heated. They are then subjected from two to three hours to a temperature of about 300deg. or 350deg. Fah.—Patent completed.

2151 T.J. MAYALL, Roxburg, U.S.A. India-rubber soles. Dated July 7, 1868.

This consists chiefly in the novel means for preserving the surface of the sheets till they are used, and in the peculiar method of roughening the sheets on the surface which is to form the outside of the soles. The surface of the vulcanized sheet which is to form the inside of the soles is temporarily covered with some woven fabric, which is removed when the sheets are used. The other surface of the sheet, which is to form the outside or bottom of the sole, is roughened by producing upon it a pattern or impression, such impression being taken from a sheet of some woven fabric or other substance of suitable texture. In practising this invention, a sheet of cotton, cloth, or other suitable woven fabric is taken, and a layer of dissolved pure india-rubber or compound which is to form the vulcanized sheet is spread. The compund consists of india-rubber, whiting, sulphur, lithat, e., or white lead, calcined magnesia, lamp black, and clay, in the following proportions:—Four pounds of the rubber, two pounds of whiting, one pound of sulphur, one pound of litharge, one-half pound of lamp black, and two pounds of clay. This compound is applied by means of an ordinary coating machine. When the compound has been spread to the desired thickness, the sheets are passed between the covered rolls of the machine, the surface of the rubber being first sprinkled with French chalk to prevent its adhesion to the rolls. The fabric and compound are squeezed or pressed together as they pass through the rolls, and the pattern or figure of the fabric is thereby impressed upon the surface of the india-rubber compound. The sheet of the material is then wound upon a receiving roller, and is left on the same till it has been cured or vulcanized of the material is then wound upon a receivi

2152 E. COPPEE, Hain-street, Pierre, Belgium. Cols wraces. Dated July 7, 1868. This consists in the construction of coke ovens, thereby the heat given off by the coking fuel may be

utilized, the gases of combustion generated in one oven being used to light the fire in or heat the adjoining oven throughout the series. The ovens are long, deep, narrow chambers, open at top for charging, and surrounded at the side and bottom with flues. These ovens are built up side by side upon a hollow bed of brickwork, within which (at one end of the ovens and at right angles thereto) run two large flues set side by side, and both communicating with a common chimney. In one of these flues is placed a cylindrical boiler, at one end this boiler takes a vertical direction, the flue being continued upwards to receive it. The ovens are grouped in couples to allow the gases of combustion of every two ovens to commingle and pass away together. Each oven is connected at its upper part (just below the crown) by means of lateral openings, with a side flue; and at bottom, the side flues of the two adjacent ovens connect by lateral openings at the bottom of, say, the first oven. The gases here commingle and then pass under the first oven. When they arrive at the end of this flue, they enter by a lateral opening the flue under the second opening, and passing along that flue, they escape into one or other of the large flues through openings commanded by dampers, which will turn the gases either into the flue containing the boiler, or in the other which leads directly to the chimney. In covered spaces formed between what may be termed the hoppers of the ovens, are pipes for discharging the gases from the burning coal into the atmosphere and other pipes for admitting air to the ovens. This air is heated in its passage through the pipes, and it is admitted into the ovens in small jets.—

—Patent completed.

2153 F. Vetth. Zurich. Straps or bands. (A communication). Dated July 7, 1868.

2153 F. Veith. Zurich. Straps or bands. (A communication). Dated July 7, 1868.

The object of this invention is the preservation of straps or bands, and to cause them to adhere better to the arms or pulleys, and consists in coating them with a mixture of train or other such oil.—Patent abandoned.

The object of this invention is the preservation of straps or bands, and to cause them to adhere better to the arms or pulleys, and consists in coating them with a mixture of train or other such oil.—Patent abandoned.

2154 J. LAWSON and E. G. FITTON. Hackling, &c. Dated July 7, 1868.

The first improvement refers to backling machines, and consists in running the sheets over three shafts, to cause them to run lighter. It is usual to run the sheets of hackling machines over a shaft at the bottom, having drums on, varying from 8in. to 12in. diameter, and over a shaft at the top as small as convenient, say, 2in. to 2jin. diameter, in which case the sheet bears heavily on the top shaft. To lessen the friction or strain on this top shaft, a third shaft is introduced, with a pulley or a drum on, to reduce the friction or bite of the sheet, and cause the machines to run easier. The second improvement also refers to hackling machines, and consists in applying a stripping motion to the sheets or hackles. A compound motion consisting of a crank or secentric and rocking shaft, through which the shank or stem of the connecting rod passes. To the end of this shank is attached the stripper, which has a backward and forward as well as an up and down motion to strip the hackles. The third improvement relates to combing machines, and consists in using one or more rotary nippers, mounted on discs or plates, in combination with an ordinary head of spiral or screw gills and fallers. The rotary nippers are arranged to open and close like a pair of tongs or pincers, and are placed on shafts or axes. The shafts are supported in grooves or slots in plates or discs, and are free to move in eccentric grooves or neams. The disc revolves on a shaft with cams tixed on it; these cams cause the nippers to open at the proper time, as they revolve round them, holding and relieving the tufts of tow or other material as desired. As the rotary nippers are hold of fallers to rake a taft, they move forward by means of the eccentric grooves on the d

move slowly whilst taking hold of or depositing a tuft.—Patent completed.

2155 T. R. Crampton, St. George-street, Westminster. Forts, &c. Dated July 7, 1863.

In constructing forts, fortifications, or other defences, according to this invention, a mould or moulds of the form of defence required is prepared on its site, and on or near thesame one or more furnaces for melting metal is erected. The metal as melted is conveyed into the moulds as in ordinary castings. The defences can thus be cast either in one piece or they may be in blocks cast separately side by side in the position in which they are to be used. It will be seen by this process, weights can be cast which it would be impracticable to transport from a foundry, and that forts or other defences of a massive character may thus readily be constructed in any position desired. Armour plates may also be fixed in front of the forts or defences constructed as above described. In some cases, forts may be constructed of an annular form, both the inside and outside walls of the ring being corrugated. In some cases, forts may be constructed of an annular form, both the inside and outside walls of the ring being corrugated, the number of corrugations being equal to the number of guns to be employed, each corrugation having one or more holes plerced, so that the gun can take an extended rane, allowing of concentrating several guns on one point, the corrugations of the inner wall being also pierced for guns; these guns can fire over the opposite side of the fort, and enable, in some cases, some of the guns to fire from the outside and some from the inside, and be so concentrated on one object. The inner and outer walls may either be made separately, and the space between them remain uncovered, or this space may be covered over with an arched roof, either cast in one piece with the walls or otherwise. Forts may also be made of a series of cupolas of a much roof, either cast in one piece with the walls or otherwise.

may fire from any port hole; these cupolas may be isolated or placed in a circle, or other convenient arrangement, so that one or more guns on the inside and outside can be concentrated in certain cases on one point. The effect of casting in masses, on the site, insures a more homogeneous structure than can be obtained by wrought iron, since heavy wrought-iron plates cannot with any certainty be made sound, and of equal quality; besides, the difficulty of securing such immense plates together in one homogeneous mass with large bolts and nuts or rivets, is almost impracticable (in a commercial sense), besides which the great number of pleces to form a built-up fort of metal is a great element of danger.—Patent completed.

2156 B. P. Walfer, Wolschempton, Printe Angle.

is a great element of danger.—Patent completed.

2156 B. P. WALKER, Wolverhampton. Driving bands.

2156 B. P. WALKER, Wolverhampton. Driving bands.

In carrying out this invention, two clips of metal are formed, space being left between the inner surfaces of such clips sufficient to receive the ends of the belts to be joined, each clip having cut out of it the part where the band occurs for the reception of part of the end of another similar clip; the band or belt is so placed within each clip as to leave space for a pin to pass through the bends of both clips (which then form a hinge), and so fasten the two clips which unite the band firmly together. The clips are formed with holes in them to receive the pins or screws necessary to hold the bands.—Patent completed.

2.2157 A. P. Peter Lipscoling.

formed with holes in them to receive the plus or screws necessary to hold the bands.—Patent completed.

"2157 A. P. Price, Lincoln's-inn. Phosphates of lime. Dated July 7, 1868.

This consists in submitting bones, coprolites, animal charcoal, or other natural or artificial phosphates, to the action of acids, such as sulphuric, hydrochloric, or nitric acids, and precipitating from the soluble portion of the result of such decomposition what is known as bibasic phosphate of lime, or of other calcareous compounds.—Patent abandoned.

2158 G Morron, Birmingham. Ornamenting fireplaces. Dated July 7, 1868.

In ornamenting the arched or curved parts of firegrates, the patentee makes the edge of the arched parts of a beading or moulding, by preference, of a nearly new semicylindrical figure, and coat or cover the beading with a strip of perforated metal is attached to the beading. The strip of perforated metal is attached to the beading. The beading may either be left plain and unpolished, or it may be polished or painted, before the application of the strip of perforated metal. The perforations in the strip of brass or other metal may be of any desired ornamental pattern. The appearance of the plain polished or coloured beading through the perforations in the metal produces a highly ornamental effect.—Patent completed.

2159 T.J. MAYALL, Boxburg, U.S.A. India-rubber tubing.

2159 T. J. MAYALL, Boxburg, U.S.A. India-rubber tubing

ornamental effect.—Patent completed.

2159 T. J. Mayall, Boxburg, U.S.A. India-rubber tubing. Dated July 8, 1868.

This consists, chiefly, in the novel combination of ingredients forming the varnish or coating, and also in a novel compound or combination of substances for forming such tubes and other articles. The coating or lining for the interior surface of the tubes or other article is composed of linseed oil and fine litharge or white lead in the proportion of one quart of oil to one pound of litharge. The substances are well boiled together, until brought to the proper thickness of body, and while hot the composition is applied, by running it through the tube to be coated or lined. To form the varnish for the outside of the tubes or other articles, the patentee mixes one quart of linseed oil with one half pound of litharge, and adds to the same about a gill of gold size. These ingredients are well boiled together, and while hot are applied to the tube with a sponge or brush. When the tube is properly varnished, it should be hung up to dry in a room or chamber suitably heated for the purpose. The improved varnish may be applied to any kind of India-rubber tubing, or of a compound consisting of india-rubber, zinc, pipeclay, gum shellac, white resin, and sulphur. The ingredients are mixed in the proportion of 4th. of india-rubber to 2lb of sulphur. This compound should be subjected for about two hours to a temperature of 260deg. Fah, more or less. The proportions of the ingredients in this compound, and in the other compounds herein described, may be varied if desired, within certain limits. Any desired colouring matter may be mixed with the varnish for coating the exterior of the tubes or other articles, which may thus have imparted to them a highly ornamental or finished appearance.—Patent completed.

2160 T.J. Mayall, Roxburg, U.S.A. Telegraph cables.

exterior of the tubes or other articles, which may thus have imparted to them a highly ornamental or ilinished appearance.—Patent completed.

2160 T. J. Mayalla, Roxburg, U.S.A. Telegraph cables. Dated July 8, 1868.

This consists chiefly, first, in the method of encasing the conducting wires of the cables with insulating compounds and materials; second, in the application to such cables of an exterior casing of vulcanized india-rubber, gutta-percha, or a combination of both substances; and, third, in a novel compound or combination of india-rubber and gutta-percha, with other ingredients, to form the exterior casing. The conducting wires of the cable may be coated in the usual manner with india-rubber or gutta-percha, or both substances combined, or compounds of the same, with other materials, and this coating may be covered, or what is technically termed frictioned, with a solution of the same substance or compound. In this condition the cable will serve for all ordinary purposes as a land telegraph cable, but for use under some circumstances it may require additional protection, which is secured by the application of the improved protective covering over the cloth wrapper, which is prepared in the following manner.—Upon a sheet of cotton or other fabric a layer of pure rubber is spread dissolved with camphine or other solvent. Over this rubber the vulcanizing substance or compound is applied, which is then cured or vulcanized in the ordinary manner. The following compound the patentee has found suitable:—Ib. of Para rubber, Ib. of gutta-percha, Ib. of zinc, 2lb. of pipeclay, ½lb. of sulphur, ½lb. of shellac, ½lb. of French chalk, and 202. of white resin. This compound should be cured or vulcanized for about 23 hours, at a temperature of about 25 dodgs, Fahrenheit; but these proportions, as well as the number of hours and degrees of heat, may be slightly varied without affecting the result. The cloth or fabric is then removed from the vulcanizing sheet, its removal being easily effected by wetting the same wi overlapping ends are thoroughly secured and made water-

tight. When the cable is to be used for a submarine or ocean telegraph, it will be necessary to strengthen the same by the use of wire rope, or platted or twisted fibrous materials, or other substance ordinarily employed in the construction of such cables. Over this wire or other strengthening material the protective covering, as above described, is applied.—Patent completed.

described, is applied.—Patent completed.

2161 C. D. Abell. Chancery-lane. Ornamenting fabrics, dc. (A communication). Dated July 8, 1868.

This consists in the application of a metallic ornamentation upon one or both sides of open or close woven fabrics. By a composition consisting by preference of white lead or zinc white, or other suitable mineral salt, diluted with linseed and fatty oils, and copal or other similar varnish mixed together in suitable proportions for producing a fluid paste. When the ornamentation is to be applied to feathers, artificial flowers, and such like articles, the use of the white lead or zinc white may be omitted in the adhesive composition.—Patent abandoned.

white may be omitted in the adnesive composition.—Patent abandoned.

2162 J. Livchak, Vienna. Aeronautical apparatus. Dated Julys, 1868.

To the balloon which the patentee describes he gives a longitudinal shape and conic ends, and so to connect it with or secure it to the apparatus by means of a net or other texture as to keep it continually in a horizontal position, and at a suitable distance from the frame or body of the apparatus, and it is preferred to enclose it in or cover it over with an air-tight cloth or light tissue, the two edges of which may be firmly secured to a loose frame connected with the central frame or body of the apparatus. The patentee constructs the frame or body of the apparatus in such a manner as to admit into its central part a steam engine or other motor being connected with and actuating a threefold set or system of cranks or cranked levers, which in their turn are joined to or connected with a series of two, four, or more casings of prismatic or any other suitable shape, being by preference that of a trilateral prism.—Patent abandoned.

2163 J. F. Cooke, Cannon-street. Copying ink. Dated July 8, 1888.

The patentee employs as a substitute for giveerine, in

2163 J. F. COOKE, Cannon-street. Copying ink. Dated July 8, 1868.

The patentee employs as a substitute for glycerine, in the manufacture of copying ink, sugar, treacle, or chloride of calcium in solution, in the same proportions as the glycerine.—Patent abandoned.

the manufacture of copying ink, sugar, treace, or culoring of calcium in solution, in the same proportions as the glycerine.—Patent abandoned.

2184 J. Holt and G. T. Coponet, Clerkenwell. Printing machines. Dated July 8, 1868.

This invention is specially applicable to that class of machines. Dated July 8, 1868.

This invention is specially applicable to that class of machines known as "Main's," and by means of a combination of mechanism the machines are caused to print alternate sheets, and "double roll" the "forme." The impression cylinder and feed-board are maintained inoperative at pleasure, for the purpose of inking up or otherwise. The parts of Main's machine which are brought directly into contact consist of the cams for actuating the impression cylinder and feed-board, which cams are fixed on the cylinder and made to surround a portion of the driving shaft of the machine, one end of which cylinder is formed to gear with a clutch; a clutch satisfy mounted on the driving shaft capable of gearing with the end of the cylinder; a spring, by means of which the clutch can be maintained in gear with the end of the said cylinder; a sliding bar, suitably guided and placed underneath and parallel with the said driving shaft; a suitable projecting arm, on the upper side of which bar a pair of friction rollers are attached to engage a cam formed with lateral projections; the cam as it revolves imparts a to-and-fro motion to the bar. This cam forms the principal part of the combination; it'ls fixed on one extremity of a shaft, placed underneath and parallel with the sliding bar and driving shaft. On the opposite side of this shaft a toothed wheel is fixed which gears into another toothed wheel of half the diameter mounted loose on the outer extremity of the driving shaft; this latter wheel is formed to gear on one side with a clutch which is placed beside it on the driving shaft, movable, as is the first-named clutch, on feathers or fixed keys in the shaft. This clutch is actuated by means of a handle or lever so as

it at pleasure.—Patent completed.

2165 J. PREST. W. MATHER, and W. DOHERTY. Chaff cutters. Dated July 8, 1868.

This consists in the novel employment and use of two peg wheels, of different sizes, screwed to and capable of sliding on to the bottom feed roller spindle, the large one to gear in at the side of the worm (as in the present machines) and the smaller one to gear under the worm. The said peg wheels are arranged on the shaft in such a manner that either may be brought in to or out of gear with the driving worm, which may be actuated by hand or by hand and pulley. The peg wheel usually placed on the top roller spindle is dispensed with.—Patent completed.

2166 W. BROOKES. Chancery, lane. Economical A.

pleted.

2166 W. Brookes, Chancery-lane. Ecaporating. (A communication). Dated July 8, 1868.

Steam, hot water, or it may be air or gas, is conducted by a passage into the annular chamber, thence into another chamber which may be called the desiceator, from which it passes into the annular chamber, and thonce to what may be called the vaporizer, from which it passes into an annular space, from which it may pass back or away by a passage.—Patent abandoned.

2167 A. J. L. B. R. J. C. Parie. Belta bands. Acc. Dated.

away by a passage.—Patent abandoned.

2167 A. J. LE BLANC, Paris. Belts, bands, &c. Dated July 8, 1863.

This consists in the manufacture of belts, bands, or ropes by means of a fabric, by preference of cotton coated with caoutchouc, and rolled on and in to one another; it is then submitted to strong pressure, in order to cause the caoutchouc to pass through and in to the pores of the fabric; the material is subsequently coated with caoutchouc and vulcanized. The invention further consists in the employment for the manufacture of belts, bands, or ropes of all kinds of woven tissues or textile fibres, woven or twisted and impreparated with caoutchouc, gutta-percha. or other gummy or resinous materials, thus giving similar advantageous results that the present india-rubber and vulcanized cotton fabric possess; they can be made of caoutchouc, prepared to resist fatty bodies with oil.—Patent completed.

2168 E. COPPER, Belgium, Crushing and washing coal.

2168 E. COPPEE, Belgium. Crushing and washing coal. Dated July 8, 1868.

The apparatus consists of two crushing mills interposed, between which are two washing vessels connected at bottom with pumps for forcing waterup, into, and through the pulverized coal. Beyond the second mill is a trans-

verse trough or gutter, along which the crushed and washed coal is carried to chambers where it is finally deposited. The following is the mode of operating with this apparatus.—The coal is fed in at the foot of the chain of buckets, by which it is raised to the upper part, where it is poured into a hopper which conducts it to a pair of fluted rollers forming the first crushing mill. By this mill the coal will be reduced to small pieces, which, falling into an incline, will be discharged into the first washing vessel, where the operation of separating from it the heterogeneous matters which it contains will commence. The crushed coal, as it leaves the crushing mill, will be received upon an inclined grating with which the crushing vessel is fitted. Along this grating the coal will pass, approaching near to a beater wheel, at each jerk or pulsation it receives from the water, which is forced into the vessel at each stroke of the pump. If it should be required to employed the coal in an unwashed state, but which is nevertheless required to be ground, the mill is provided with two pairs of rollers, the one pair for coarsely breaking up, and the other pair for completing the crushing. The inclined plane under the mill is so set that the ground coal may fall into a shoot placed under the mill, and be conducted to the trucks provided to receive it. receive it.

receive it.

21:0 T. Kerr, Paisley. Firearms. Dated July 8, 1868
This consists in providing a hollow socket which projects rearwards from the breech end of the barrel; the rearmost end of the socket is made completely circular, whilst the intermediate part is cut away, leaving a semi-circular cavity. Through the circular extremity a sliding breech-piece passes, which can be forced by the hand close against the end of the barrel, and withdrawn therefrom with great rapidity. Towards the rearmost end of the sliding breech piece an encircling collar is fitted, this having a handle or lever formed on it so that in turning the collar by applying the hand to the handle or lever, that part of the handle or lever, as well as a projection on the opposite side of the collar, enter inclined slots cut in the circular part of the socket, so that by depressing the handle or lever firmly therein the breech-piece is forced against the breech end of the barrel.—Patent abandoned.

2170 W. TASKER, Andover. Elevating straw, &c. Dated

handle or lever firmly therein the breech-piece is forced against the breech end of the barrel.—Patent abandoned. 2170 W. TASKER, Andover. Elevating straw, &c. Dated July 8, 1868.

The machinery is so constructed that it may either take the straw direct from a thrashing machine, being worked therefrom or combined with the front or back carriage of the straw elevator without the necessity of raising or lowering the whole machine for either mode of working. The framing to which the elevator is attached, and also the framing of the elevator itself, is constructed of angle or other shaped metal bars, which may be riveted together. This framing is mounted on a front and back carriage. The invention consists chiefly in attaching to or forming on the front or back carriage of the elevator gear work or gearing, to be worked by horses or other animals passing round or under such elevator, giving motion to the same, the entrance to the trough or spout being always sufficiently low to receive the straw from a thrashing machine, if desired. The gearing may be actuated with the front or back carriage of the elevator. By this means the inconvenience (when used as a ricker in hay time and harvest) of employing a separate gear work is avoided, whilst at the same time the necessity of vertical adjustment of the whole machine is dispensed with.—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT.

Dated January 12, 1868.

86 C. M'Dougall and C. H. Eden, Manchester. A ladies' umbrella and dress suspender.

87 W. E. Gedge, Wellington-street, Strand. An improvement in power looms. (A communication.)

88 A. Henry, Edinburgh. Improvements in firearms and ammunition.

89 A. P. Price, Lincoln's Inn-fields. Improvements in the production of colours from napthaline. (A communication.)

the production of colours from napthaline. (A communication.)

90 B. Hunt, Serle-street, Lincoln's Inn. Improvements in water meters. (A communication).

91 Sir F. Sykes, Isenhurst, Sussex. An improved mode of, and apparatus for, defending ships, forts, and other vessels or structures against injury from projectiles.

92 A. V. Newton, Chaneery-lane. Improvements in knitting machinery. (A communication).

93 D. L. Coates and Q. Dunlop, Belfast, and W. Orr, Ligoniel, Antrim. Improvements in couplings and wheels for shafting and gearing.

94 C. E. Brooman, Fleet-street, City, patent agent. Improvements in the construction of velocipedes. (A communication).

95 G. 1V. Osborne and A. J. Peerless, Rahere-street, Goswell-road, Middlesex. An improved ball valve or cock.

Dated January 13, 1868.

96 H. [Aitken, Falkirk, Stirling. Improvements in lamps.

97 S. Jellymann, Cannock, Staffordshire. Improvements in reaping and mowing machines.
98 C. J. Gunther, Mark-lane, City. Improvements in salting and preserving meat. (A communication).
99 P. M. Barnett, Aberdeen. Improvements in fixing and securing wooden keys in railway chairs.
100 J. Steel, Glasgow. Improvements in sanitary arrangements to be substituted for water-closets.
101 L. Sterne, Great Queen-street, Westminster, and J. A. Jaques and J. A. Fanshawe, Tottenham, Middlesex. Improvements in the manufacture of clastic rubbers.
102 J. Parker, Lifford-road, Camberwell, Surrey. Further improvements in motive-power apparatus applicable for propelling vessels and for preventing vessels from foundering, and for forcing water, and for other purposes.

purposes.
103 L. Handart, King-street, Clerkenwell, Middlesex. A 103 L. Handart, King-street, Clerkenwell, Middlesex, A new tool or mould for moulding or casting dises, or wheels requiring to have letters, characters, numerals, or other devices or designs formed around or about their circumferences in metal or other materials.

104 J. Schlosser, Finsbury-place, Middlesex. A new or improved self-acting metallic packing for parts of sterm, air, zas, water, or other machinery or apparatus in which packing is required.

105 W. R. Lake, Southampton-buildings, Chancery-

lane. An improved method of, and devices for unlting the ends of pipes or tubes. (A communication).

106 C. P. Coles, Mountfield, Bonchurch, Isle of Wight. Improved means of protecting the bottoms of ships or other submerged structures from fouling.

Dated January 14, 1869.

107 G. D. Kittoe and P. Brotherhood, Compton-street, Clerkenwell Midelesex. Improvements in valves.

108 W. M'Donnell, Limerick. Improvements in, or addition to churns, parts of which are applicable to other Nurroses.

purposes.

109 R. Watson, Birmingham, and B. Dangerfield, West Bromwich, Staffordshire. Certain improvements in keysless and stop work employed in chronographs and other similar timekeepers for the measurement of fractional portions of time.

110 J. R. Hodgson, Limehouse, Middlesex. Improvements in life buoys, boats, or floating apparatus to be employed for rescuing persons in case of shipwreck or disaster at sea.

111 T. Mortlock, Singleton-street, Hoxton, Middlesex. Improvements in appearance.

disaster at sea.

111 T. Mortlock, Singleton-street, Hoxton, Middlesex.
Improvements in apparatus for levelling, furrowing, and dressing millstones.

112 E. P. North, Birmingham. Improvements in pocket

dressing millstones.

112 E. P. North, Birmingham. Improvements in pocket railway reading lamps.

113 H. Vavasseur, Summer-street Southwark, Surrey, and C. M. Wade, Furnival's Inn, Middlesex. Improvements in the permanent way of railways, which improvements are also applicable for works where wedges are used. (A communication).

114 A. V. Newton, Chancery-lane. Improvements in resping and mowing machinery. (A communication).

115 W. E. Newton, Chancery-lane. An improved stop motion and regulator for steam pumps. (A communication).

116 J. H. Kitson and J. Kirby, Leeds. Improvements in movable grates for steam boller or other furnaces.

117 T. Cook, Old Kent-road, Surrey, and J. Watson, Victoria Chambers, Westminster. Improvements in presses for expressing olls and other liquids.

118 A. M. Clark, Chancery-lane. Improvements in preced-loading firearms and cartridges. (A communication).

tion).

119 T. Birkett, Birmingham, and H. Scott, West Bromwich, Staffordshire. Improvements in breech-loading

Dated January 15, 1868.

120 H. L. Harris, Somerset-street, Aldgate, City. Improvements in the construction of [packing cases and boxes.]

120 H. L. Harris, Somerset-street, Aligate, City. Improvements in the construction of spacking cases and boxes.

121 C. H. Lea, Staffordshire. Improvements in apparatus for opening, closing, and locking rallway level crossing or other gates, which apparatus acts simultaneously on near or distant railway signals, and partly controls the working of the crossing signals, also improved apparatus for independently actuating a semaphore signal for signals) placed at the crossing, and partly controlling the working of the opening and closing apparatus; also improved apparatus used in connection with the above for locking the gates when closed, and improved means for raising or lowering such gates when necessary.

122 J. Steel, Glasgow. Improvements in apparatus for washing or cleansing casks, vats, or similar vessels.

123 A. de P. Chance, Birmingham. Improvements in step-ladders. (A communication).

124 J. T. Smith, Barrow-in-Furness, Lancashire. Improvements in converting vessels used in the manufacture of iron and steel.

125 H. Fowkes, Manchester. An improved rod to be employed for cleaning rifled or smooth-bore gun barrels, in the rollers and furniture for window blinds.

127 W. Tijou, Great George-street, Westminster, and W. Whieldon, Westminster Bridge-road, Lambeth, Surrey. Improvements in apparatus for facilitating the getting of coal, stone, and other minerals.

129 W. H. Brookes, Sheffield. An improved fastener for doors and windows. (A communication).

130 P. Spence, Newton Heath, Manchester. Improvements in the production of sulphate of potash for the manufacture of alum.

131 T. Howcroft and A. M'Gregor, Bedford Leigh, Lancashire. Improvements in reaping and mowing ma-

Improvements in reaping and mowing ma-

chines.
132 E. Craddock, Camberwell New-road, Surrey. An improved portable punch for punching metals.
133 M. Boyce. Abchurch-lane, City. Improvements in apparatus for scoring at whist and other games.
134 A. H. A. Durant, Avenue-road, Shepherd's Bush, Middlesex. Improvements in the manufacture of oil from castor and other oleaginous seeds or berries.

Dated January 16, 1869.

135 T. A. Warrington, Carlton-road, Kentish Town, Middlesex. Certain improvements in the construction of

Middlesex. Certain improvements in the construction of spoons.

136 J. T. Bintley, Kendal, Westmoreland. Improvements in the mode of, and apparatus for connecting or joining together the ends of rails in constructing the permanent way of railways.

137 S. Russell Burton-road, Brixton, Surrey. Improvements in velocipedes and manumetive carriages.

138 R. Craig, Newbattle Mills, near Dalkeith, Midlothian, Scotland. Improvements in machinery or apparatus for the manufacture of paper.

139 J. Jeavons and W. Waplington, Atlas Steel and Iron Works, Sheffield. Improvements in the manufacture of iron and steel, and in the apparatus connected therewith.

of iron and steel, and in the apparatus connected therewith.

140 J. G. Johnson, Coombe Fields, Warwickshire. Improvements in self-acting signalling apparatus applicable for use on railways or tramways, and for other purposes.

141 J. H. Johnson, Lincoln's Inn-delds. Improvements in the manufacture of casks, tubs, and other like receptacles, and in the machinery or apparatus employed therein. (A communication).

142 H. A. Silver, Bishopsgate Within, City. Improvements in apparatus for cooking and other purposes.

143 J. Bourne, Leith, Scotland. Improvements in propelling versels.

144 J. Loader and W. H. Child, Finsbury, Middlesex. Improvements in ateam boilers.

145 W. and S. Bottomley, Milnrow-road, Rochdale, Lancashire. Improvements in the couplings of rollers for cotton, silk, woollen, worsted, and other machinery.

146 W. Thomas, Cheepside, City. Improvements in the manufacture of boots and shoes.

147 J. B. Whitehall, Goldsmith-street, Nottingham. Improvements in machinery and apparatus for the manufacture of looped fabrics.

148 F. Braby, Camberwell, Surrey. Improvements in the commercial manufacture of sulphate of ammonia.

149 L. B. Phillips, Queen-square, Middlesex. Improvements in means for obtaining in metals or alloys facsimiles of works of art, and designs in relief and intaglio, composed of metals, wood, gems, wax, and other substances, and also of type and parts of machinery.

150 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in the manufacture of figured shawls and other woven fabrics. (A communication).

151 M. Henry, Fleet-street, City. Improvements in moulding metal articles. (A communication).

Dated January 18, 1869.

152 W. Pidding, Walcot-square, Surrey. Improvements in the mode or modes of the production or manufacture of cat piled mosaic, mosaic textile and tesselated fabrics, in the treatment of materials used, and in machinery and apparatus used for the said purpose.

apparatus used for the said purpose.

153 W. H. Platt, Ashton-under-Lyne, Lancashire. Improvements in looms for weaving.

154 N. Voice, Handcross, Sussex. Improvements in apparatus connected with closets and urinals.

155 C. Catlow, Burnley, Lancashire. Improvements in looms for weaving.

156 J. D. Thomas, Liverpool. An improved artificial

bust.

157 P. Oldfield, Bradford, Yorkshire. Improvements in machinery for preparing and combing wool or other brous substances.

153 R. H. Clark, Eavsham, Norfolk. Improvements in the manufacture of silk cloths, and in fixing them on silk bolting reels for dressing meal and flour.

159 G. R. Postlethwaite, Birmingham. Improvements in machinery for the manufacture of screw puts belts.

bolting reels for dressing meat and flour.

159 G. R. Postlethwaite, Birmingham. Improvements in machinery for the manufacture of screw nuts, bolts, spikes, rivets, screw blanks, and other like articles.

160 J. W. Price, Frogmore-street, Abergavenny, Monmouthshire. Improvements in the manufacture of horse shoe naits and other nails, and in machinery to be employed therein.

161 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in propelling machinery for canal boats and other vessels, parts of which improvements are applicable to the propulsion of vehicles on land. (A communication).

162 G. Brown, Beaumont-place, Edinburgh. Improvements in gas meters and other measures by apparatus for registering the passage of gas and other bodies.

163 J. H. Johnson, Lincoln's Inn-leids. Improvements in the burning of bricks and other like articles, and in the kilns employed therein. (A communication).

164 A. M. Clark, Chancery-lane. Improvements in the manufacture and rething of sugar. (A communication).

the manufacture and relining of sugar. (A communication).

165 H. and J. Parnall, Bristol. Improvements in the construction of centres and bearings of scales, scale beams, and weighing machines.

166 W. T. Eley, Gray's Inn-road, Middlesex. Improvements in the construction of cartridge cases.

Buffer Springs for Locomotives and Railway Trucks, Valves, Sheet, Washers, Suction and Delivery Hose, Tubing for Gas. &c., Machine Belting, Elastic Steam Packing in Rope, Sheet, and Rings, &c., &c.

#### EBONITE.

Sheet, Pumps, Taps, Tubing, &c., for acids and vinegar; Photographic and Surgical Articles, Speaking Tubing, &c.

#### GUTTA-PERCHA.

Sheet, Tubing, Pump Buckets, Valves, Machine Belting, Vessels for chemicals and acids, &c.

#### WATERPROOF.

Clothing, Hot-Water Cushions, Matting, Ground Sheets, Aprone Waggon Covers, &c., &c.

#### TELEGRAPH INSTRUMENTS.

Insulators, Batteries, Insulated Wire, and every description of Telegraph Apparatus and Stores. Vilcanised India-rubber specially prepared to withstand the action of tropical climates.

WORKS, SILVERTOWN, ESSEX. B 41

THE BEST REMEDY FOR INDIGESTION.

ORTON'S CAMOMILE PILLS are confidently recommended as a simple but certain remedy for ludigestion. They act as a powerful tonic and gentle aperient, are mild in their operation; safe under any circumstances; and thousands of persons can now bear testimony to the benefits to be derived from their use.

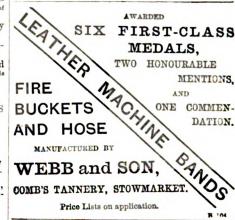

Sold in bottles at 1s. 13d., 2s. 9d., and 11s. each, in every town in the Kingdom.

Soid in bottles at 18, 14d., 28, 2d., and 11s, each, in every town in the Kingdom.

CAUTION:—Be sure to ask for "NORTON'S PILLS," nd do not be persuaded to purchase the various inditations.

A 54

DUMPING MACHINERY of every description for works of drainage and irrigation, the supply of towns, villages, estates, manufactories, &c. &c.—Apply to GWYNNE and Co. Engineers, I-sex-street Works, Strand, London, W.C. Large Blost stamps.

QUARIUMS made upon an improved A principle. Warranted not to leak. Glass all round; tastefully mounted; gilded, and fixed on polished stands; suitable for the drawing-room. 16in. by 12in. by 10in. 16s. each. Goldfab Globes beautifully mounted, to hang or stand, and to carry flower vase; suitable for the window, luncheon bars, and public rooms; a pretty ornament, 10in., 5s. each. Engravings and particulars on application.

Manufacturer of the Improved Railway Carriage Key, made to close, for the waistocat pocket, post free for 14 stamps. No railway traveller should be without one.

### MECHANICS' MAGAZINE.

LONDON: FRIDAY, JANUARY 29, 1869.

SEWERAGE OF GLASGOW.

T the time that the metropolitan drainage A works were undertaken it was felt by some that the proposed plan of discharging the whole sewage of London into the Thames was not that which should have been adopted. In the incipient state of the sewage question at that period, although one cannot commend the system carried out, yet it may be fairly excused. But no such excuse can be pleaded now for those who advocate the execution of methods so suicidal. The true and only principle upon which sewage can be disposed of, with a proper regard to sanitary considerations, existing habits, and opinions, and with a chance of producing a remunerative return, is that of application to the soil. It will scarcely be believed that, notwithstanding the universal recognition by not only every engineer, but by every man of common sense, of the truth of this self-evident proposition, it is proposed to repeat the "wilful waste" upon a large scale in the waters of the Clyde.\* For some time past the question of utilizing their sewage has occupied the townspeople and local subhorities of the city of Clesgow and like authorities of the city of Glasgow, and, like wise men, they called in the assistance of eminent engineers to help them towards arriving at a solution of the many difficulties invariably attendant upon extensive projects of a similar nature. In accordance with in-structions received, Messrs. Bateman and Bazalgette prepared plans for the utilization of the sewage, which were founded upon the principle that we have already laid down as the only correct standard in such cases. It is not to be supposed that because plans for sewage or any other works are prepared by eminent engineers they are not liable to criticism and fair animadversion; and in the details of those to which we have referred there may very possibly be many points deserving of reconsideration. But it is one thing to suggest amendments, to modify or to extend, and another to attack the principle or basis upon which a project is founded.

Engineers continually differ in the means

they adopt for carrying out works, but no competent professional men ever differ about the principle upon which those works are based. The former constitutes each man's individuality, and serves to bring out his own especial genius and ability, while the latter demonstrates the unity of competent professional opinion. Notwithstanding the incontrovertible veracity of this statement. that it is seriously proposed by the writer to discharge the sewage, "after a short and rapid run, directly into the river." Such a course is not only contemplated, but the means of accomplishing it are entered fully into, and the prospective advantages of measures so suicidal and opposed to all plain sense, are attempted to be proved. Although our duty is simply to point out the professional errors—both theoretical and practical into which the author falls, yet we cannot refrain from commenting upon the somewhat egotistical manner in which he claims for "his plan," which is opposed to the opinions held by avery professional manual held by every professional man, every advantage under the sun, while at the same time he denies to that of Messrs. Bateman and Bazalgette the possession of any merit whatever. One of the main errors into

• See "Sewage Irrigation: being a Second Letter addressed to the Hon. the Lord Provost," By MICHAEL SCOTT, C.E., London.

which Mr. Scott falls is the supposition that the advocates of sewage irrigation argue "a particulari ad universale," and that they consider the successful application of sewage upon a comparatively small scale is a guarantee for its success upon one more extensive. We do consider that the utilization of sewage will be successful upon a large scale, and, in fact, that it will never be thoroughly successful until it is applied upon an extensive scale, but not because it has hitherto proved so when tried in a limited sphere. We consider the success of the utilization of sewage to depend not upon the scale of its application, but upon the sound and unimpeachable truth of the principle upon which it is based. It is well to be able to distinguish between simple cause and effect and conclusions deduced from analogical reasoning.

In reading the report of the commission appointed to inquire into the best mode of distributing the sewage of towns and applying it to beneficial and profitable use, we are forcibly reminded of that issued over twenty years ago to inquire into the application of iron to railway structures. The same uncertainty and want of foresight prevails in both. The Sewage Commissioners report that sewage is "quite inappropriate for application on a comprehensive scale to arable land for corn and other ordinary rotation crops." This statement is simply so much nonsense, and the fallacy of it has been already demonstrated with a degree of certainty sufficient to convince all but those who are wilfully blind to the fact. Similarly, the Railway Commission of 1848 reported respect-ing the use of open-web bridges that "they were of doubtful merit," and in plain terms expressed their fears of the safety of bridges constructed upon that system. Now, we have a couple of railway bridges over the Thames presenting magnificent specimens of that type of design, besides innumerable examples in all parts of the country. So much for the reports of Commissions. In treating the Clyde as a sewer, it is expected, by the influx of a large quantity of fresh or sea water, to neutralize the noxious and injurious action that must be necessarily set up. is an utter fallacy, and will be found so in every case. It is true that there is a peculiarly purifying influence exerted by large volumes of uncontaminated water and air upon sewage, but the remedy is only partial—never

complete. After the results that have attended the discharge of the London sewage at Crossness, the transporting and purifying action of tidal waters is a subject that now admits of but one answer. A grave disadvantage of relying upon these agents to effect the deodorization and removal of town sewage is that their inefficacy is in a continually increasing ratio with the duration of their action. Were it granted that during the first year they would effect the desired object, they would be found to fail more and more each succeeding season. It is impossible to totally remove by these means all vestiges of the sewage matter. Some will inevitably remain, and constitute a nucleus around which more will accumulate, until the once clean and uncontaminated banks will become like even unto the shores of the Thames at Erith and Greenhithe. There can be no question that the plan of Messrs. Bateman and Bazalgette for the utilization of the sewage of Glasgow is admirably adapted for its purpose. It is based upon the only correct method of dealing with sewage, which consists in removing it rapidly and effectually from the vicinity of human habitations, ceasing to discharge it into rivers, thereby converting them into gigantic sewers, and applying it instead to the fertilization of the soil. To discharge any sewage into a river, as proposed by the author of the letter referred

prudence. It does not signify what is to be subsequently done with it, whether it be purified in reality, or only in imagination, as in the case before us; the very act of dis-charging a single drop of sewage, diluted or undiluted, into a river should be sufficient to hopelessly condemn any plan containing that feature in its composition. To pour sewage into a river and then to attempt to neutralize it by purifying agents is exactly similar to presenting a person with a poisoned draught, and then administering an ineffectual antidote.

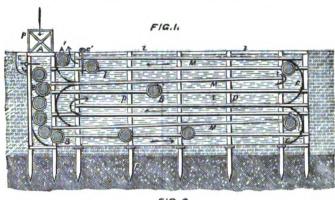

#### PRESERVATION OF IRON SHIPS.

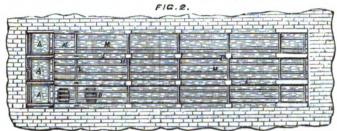

NUMBERLESS as have been the plans devised for preserving the vised for preserving the bottoms of iron-built ships, and for preventing their fouling, the list still continues to increase. Amongst the most recent and successful attempts in this direction is that of Captain Cowper P. Coles, R.N., C.B., to which we briefly alluded last week. Captain Coles has been for some time past engaged on a series of experiments in Portsmouth Dockyard, with the view of solving the problem in question. About a week since, an iron-built mortar vessel, which has lately been doing duty as a movable coal depôt, was placed in the "Warrior" dock at Portsmouth, and her bottom carefully examined. On the bottom of this vessel, for several years past, different kinds of compositions for the preservation of the bottoms of iron ships and for the prevention of their fouling, have been tested and periodically reported upon by the Shipwright Department of the dockyard for the information of the Admiralty. On the bottom of this vessel are two patches of cement composition applied on the plan proposed by Captain Coles, one of which was put on four, and the other three years since. The efficiency of these preservative cements has been satisfactorily proved by having portions of them cut away from the vessel's bottom with a chisel, when the iron plates underneath were found in perfect preservation, and as free from outer deterioration of any kind as on the day the cement was first laid over them. The anti-fouling experiment has been equally successful. In November, 1867, the last occasion on which the vessel was in dock, a patch of the cement was laid on the bottom plating under the bilge, and, before drying, was coated with a copper facing in the form of dust or filings. This patch now, after the vessel has been quite fourteen months in the water, is found to be quite clean and free from any deposit whatever, fully answering all the require-ments that would be expected from a sheet of copper fixed in any similar position. results, therefore, so far, are highly satisfactory, and if they continue to be so, and are accompanied by corresponding commercial advantages, another honour will attach to the gallant captain's name.

But Captain Coles is not the only one to whom credit is due for his exertions in prevent ing fouling and corrosion, inasmuch as within the last few days the results of some trials of another invention for the same purpose have reached us. The inventor, in this case, is an artizan—Mr. William Welch, of Portsmouth -who by patient perseverance, natural intelli-gence, and careful observation during three or four years, has invented and applied a composition which combines all the necessary qualities, being self-adhesive, preservative, and anti-fouling. With the sanction of the Lords of the Admiralty, it has been tried on several of her Majesty's ships, and notably on the bottom of the "Urgent" troop ship. After nearly two years' trial of the composi-tion on that ship, it was found to be as clean as the first day it was put on, although, in the meantime, the "Urgent" had been in all parts of the world. It has since been tried on other vessels, and recently on the "Her-cules." We understand the mercantile to, is a proceeding that should be scouted as cules." We understand the mercantile a direct violation of all laws of economy and marine are about to adopt it, and that the

#### STORING PETROLEUM.

Peninsular and Oriental Company have ordered a test application of it to one of their vessels. The composition has been patented by Mr. Welch. There can be no doubt that on the proved success of either of these in-ventions there hangs a large fortune. At present, it appears to be a fair race between Captain Coles and Mr. Welch, and may the best man win.

#### STORING PETROLEUM.

O such a pitch has the danger of storing and transporting mineral oils and essences of an inflammatory character reached, that many of the means originally available for conveying them from one place to another are now closed against them. It is not without reason that these precautionary measures have been adopted, as the numerous fatal catastrophes that have occurred in magazines, and storehouses, railway trains, and steam-boats, abundantly testify. So far as the material itself is concerned, the loss, commercially speaking, of a large quantity, is not a trifle, to mention nothing of the enormous consequential damages that attend the explosion and combustion of so inflammable a substance. The probability, or, rather, the risk of the contents of any cask, barrel, or other receptacle, in which mineral oils may be placed, being fired, and so communicating the mischief to other objects is very materially increased by the leakage or evaporation that is continually taking place, and which seems, hitherto, to be a feature inseparable from the present means in practice for preserving it.
Wooden casks still remain the favourite receptacles for petroleum and other mineral There are many and valid reasons for their being so. Among others, are their shape and strength, which is due to their peculiar form, their comparatively small price, relatively large capacity, and facility for manipulation and stowage. In spite, therefore, of many attempts made to introduce iron vessels of different shapes and sizes, the old material, timber, is not yet dispossessed of its sphere of utility in this particular instance.

Upon the arrival of a vessel laden with a cargo of this dangerous character, there are no other places to store it in than the usual cellars or sheds that are appropriated as well to a host of other miscellaneous articles. The defective nature of such an arrangement is visible at a glance. Another plan of empty-ing the contents of the casks into a single large reservoir, is one that were it once accom-

plished would leave nothing to be desired. It is in the task of accomplishing it that the danger lies. The successive handling and knocking about of the barrels under operation, is perilous in the extreme, and one that could scarcely be regarded justifiable anywhere in the vicinity of a large town or city. It has also been proposed to bury the casks in the ground, but it would be difficult to exercise a sufficient surveillance over them when in this situation. The principle upon which the greatest reliance may be placed, is that of immersing the casks containing the petroleum in water. Under these circumstances, it is impossible for the contents to take fire, and, it is also alleged, that the water causes the wood to expand, and, by completely closing the seams, prevents all leakage. of this plan is unquestionably sound, and will receive the assent of everyone, but no such unanimity of opinion will prevail respecting the best practical methods of accomplish-ing the operation. There is not merely the manipulation, the storage, and the general arrangement of the cask to be taken into consideration, but, in addition, the difficulty of keeping the casks under the surface of the the casks under the surface of the protecting fluid when they are once placed there. This last is of more importance than may at first sight seem probable. The upward pressure upon an ordinary cask of petroleum, totally immersed in water, is 100lb. and that upon a similarly shaped receptacle, containing essential oil, amounts to nearly 125lb. Calculating from these data, a row of six barrels, ranged about two to every square yard, would require a downward pressure of over 1,350lb. to keep them in their place. Consequently, the obstacles to be surmounted consequently, the obstacles to be sufmointed consist, first, of the actual immersing of the casks; second, of their maintenance in their position; and, third, of their adjustment in a manner that would allow of all, or any of

them, being withdrawn with facility.

The plan proposed by M. Mathéi is to make the upward pressure of the water subservient towards effecting the object in view, and the plan and longitudinal section repreand the plan and longitudinal section represented in the accompanying cuts will serve to illustrate the mode he adopts. In a reservoir, the size of which will depend upon the number of casks proposed to be stored, two rows of piles, p, are driven deep enough into the ground to get a firm hold, and tied together by transoms, so as to counteract the vertical force already alluded to. These piles are arranged so that the cask B can be moved in any direction that may be required, and tory annual examination, made when at rest, also to admit of openings into the reservoir internally as well as in the flues. To accom-

or magazine at A. To the piles, the spacing or magazine at A. To the piles, the spacing of which is regulated by the resistance to be overcome, are attached, by means of timber or metal crosspieces, long planks M (see fig. 2), forming a series of consecutive and superimposed inclined planes. According to the size of the casks, and the density of the liquid contained in them, so must the degree of inclination of these planes be arranged. Longitudinal timbers, L, prevent the barrels from deviating laterally during their passage up the inclines. The barrels pass from one incline to the next, by means of the semicircular passages C C (see fig. 1). There is a sliding bar C, at the entrance A, to prevent the barrels rising up again after immersion; and the opening for their egress A' is furnished with a similar apparatus. On referring to fig. 1, it will be seen that the barrels are immersed one on top of the other, until the well or pit A is filled, and the cask first immersed has reached the bottom. Arrived here, being still acted upon by the upward pressure of the water, it travels along the inclined planes, M, until it reaches the opening for egress at A', where it is retained under the surface of the water by the apparatus C 1. Since the size of the passages are so adjusted that the casks cannot pass one another in their ascent, they range them-selves in regular order, until, either as many are stored as are required, or until the magazine is completely filled. It has yet to be shown how the pressure necessary to cause the casks to sink to the bottom of the pit A is obtained. The doors P of the entrance pit A are so constructed to open upwards, and, in fact, to constitute a prolongation of the entrance itself. In this space a number of casks are piled, of a weight sufficient to sink the others consecutively. When the magazine is filled, the bar C is run across When the the opening, to keep the casks from rising; the supernumerary casks are withdrawn, and the doors closed. From the extreme simplicity of the whole operation, this plan is deserving of trial, in all cases where, from unavoidable circumstances, it becomes indispensable to store up large quantities of petroleum and essential oils. In point of cost and first outlay, this method appears capable of competing with any other that has been proposed with the object of accomplishing the same result.

#### BOILER INSPECTION.

WE have this week received the closing W report, for the past year, of Mr. Fletcher, the chief engineer to the Manchester Boiler Association. Having always been warm advocates of boiler inspection, we cannot let the present opportunity pass of recording a few facts and impressions derivable from the report in question. The first fact realized after a perusal of the document is one of the most important and significant of any. It is that no explosion has occurred to any of the boilers under the charge of the any of the bollers under the charge of the above Association during the year, while to this it may be added, that no boiler has ever exploded which the Association has guaranteed. This fact says much for the soundness of independent boiler inspection, and we see no reason why the same return may not be made every year, if the insured parties will only co-operate with the officers of the Association by accepting the suggestions for their safety, as well as by affording facili-ties for the examination of their boilers, and above all by intrusting them to the charge o f ordinarily competent men, instead of to mere labourers, as is but too often proved to be the

The Association does all it can to further e interests of humanity. It adopts the the interests of humanity. It adopts the principle of the most liberal inspection, and no boiler is guaranteed unless on a satisfac-

Digitized by Google

plish this with so many boilers, and, at the same time, to make the examinations when the boilers can be best laid off, so as not to inconvenience the members, appears to be by no means an easy matter, and has only been accomplished by making the utmost use of general holidays, as well as of local wakes, and other times of stoppage. We are sure it would be a matter of very great advantage to both parties if those members who cannot lay off their builers at the ordinary periodical visits for entire examinations, would avail themselves of their own local holidays, rather than of the general ones, when there is a complete run upon the office for special visits. To meet these demands at all, it has been found necessary at such times to lay aside all the other duties of the Association, and for the whole staff to turn out as inspectors. In this way, the number of entire examinations for the past month, returned at the commencement of the report, viz., 204, were accomplished, a considerable portion to them being made at the Christmas holidays. The total number of entire examinations during the past year has been 2,060, which, we understand, is the highest point ever attained since the formation of the Association. This result has been attained at a considerable cost, but it has been thought better to expend the funds of the Association rather on careful examinations than in the payment of compensation, upon the principle, we presume, that prevention is better than cure. Competent inspection, however, is found by experience to be a most expensive article-much more so than compensation; so that it would be to the advantage of the Association's exchequer to reduce its staff of inspectors, and carry a portion of the balance to the credit of the compensation fund. But far more praiseworthy motives are at the bottom of the proceedings; the fundamental principle of the Association is the prevention of explosions and the saving of human life, and so it merges its own interests in those of the community at

large.
We have already observed that no explosion has occurred during the past year to any boiler enrolled with the Association. On the other hand, 45 have occurred outside its ranks in different parts of the country, by which 117 persons have been injured, 57 of them fatally. In 32 cases the scene of the catastrophe was visited, and a careful investigation made by officers of the Association. have more than once drawn attention to the verdicts given by coroners' juries in respect of accidents of this nature, and there can be no doubt that in many cases during the past year the investigations conducted by coroners, in consequence of boiler explosions, have been most unsatisfactory. But little light has been thrown on the true cause of the disasters, and the stereotyped verdict of "Accidental death" has been given in almost every case, which has at least failed to stimulate any preventive measures, if it has not actually hindered them. Deaths from boiler explosions may be accidental legally, but they are not so mechanically. The inveterate habit still prevails of attributing almost every explosion to shortness of water, through the neglect of the attendants, though too frequently the poor fellows have been victimized by working bad boilers, the offspring of bungling boiler making, and commercial greed. Mr. Fletcher insists upon the importance of coroners being empowered in all cases to call in competent engineering assistance. A searching examination should be made in each instance, as well as the truth plainly spoken. Finally, Mr. Fletcher very justly observes:-- Were the press provided in this way with faithful particulars, and those who lead to the slaughter of their work-people, by the use of bad boilers, brought to the bar of public opinion, it is thought such a step would of itself do much toward the a step would of itself do much toward the prevention of steam boiler explosions, which now recur on an average at the rate of one the dark room. He says that in summer the "The Best Light for Taking Photographs,"

per week, and destroy from 60 to 70 lives per annum. The experience of the past year suggests as a corrective for boiler explosions, investigation and exposure."

#### IMPROVEMENTS IN PHOTOGRAPHY. No. II.

NEXT in order, the almanack of the "Photographic Name" tographic News," containing the cream of the results obtained by the best of its contributors for the past year, demands our atten-tion. Mr. H. P. Robinson, in an article upon development and intensification, points out, as a hitherto unnoticed fact, that if the developer be allowed to remain quietly upon the exposed film, the resulting picture will be less hard, and contain more detail in the shadows, than if the developer be kept in constant motion. The knowledge of this little fact, should it be properly substantiated, is of considerable value to photographers, because it affects the character of every picture taken by the wet process. A good endeavour is made by the editor of the journal to account for the phenomenon theoretically. He suggests that when the developer is motionless upon the plate, the high lights, after receiving a strong deposit of silver, have a layer of proportionately weakened developer above them, and the stronger part of the developer is left more immediately in contact with the shadows which require bringing out. If, on the contrary, the developer be kept in constant motion, so as to be of the same strength throughout its whole bulk, the silver is thrown down in a much larger proportion upon the places where the light has acted most, and the shadows are therefore brought up to less intensity. We think, from observation, that it is the habit of nearly all photographers to keep the developer in constant motion upon the plate, but the valuable fact just stated, should it be substantiated, will certainly modify future developing operations very considerably. It places a power in the hands of the photographer of increasing the hardness or softness of his picture, according to the motion he chooses to give to the plate during development.

Mr. Jabez Hughes calls attention to a simple method, devised by Mr. Phillips, of keeping wet plates in a fit condition for use for many hours. It consists simply of placing them in a bath of distilled water till wanted, after taking them out of the nitrate of silver. After exposure and before development, the plate must be redipped in the nitrate of silver bath; a dip of two or three seconds is not enough, but from thirty to sixty seconds will do. Mr. Hughes asserts that there is no loss of sensitiveness whatever in the plate from this treatment, and that there is great immunity from stains and defects. The only point requiring care is to select good distilled water, as bad water would make the plates fog. Of course, this plan is only useful where long exposures in the camera are necessary, or where the plate has to be carried to a long distance from the operating room before insertion in the camera. Impure distilled water is also a source of a very great number of failures in the dry processes, as Mr. William England points out in a contribution on this subject. This experimentalist has found impure water to produce insensitive dry plates, giving hard pictures, covered with granular markings. After trying several ways of increasing the purity of common water by chemical means and by filtration, he met with nothing but failures, and finds that the only remedy is to set up a still to obtain the large quantity of pure water neces-

sary in dry-plate operations.

Mr. Valentine Blanchard, the photographer who produced the well-known instantaneous views of the streets of London, has an article

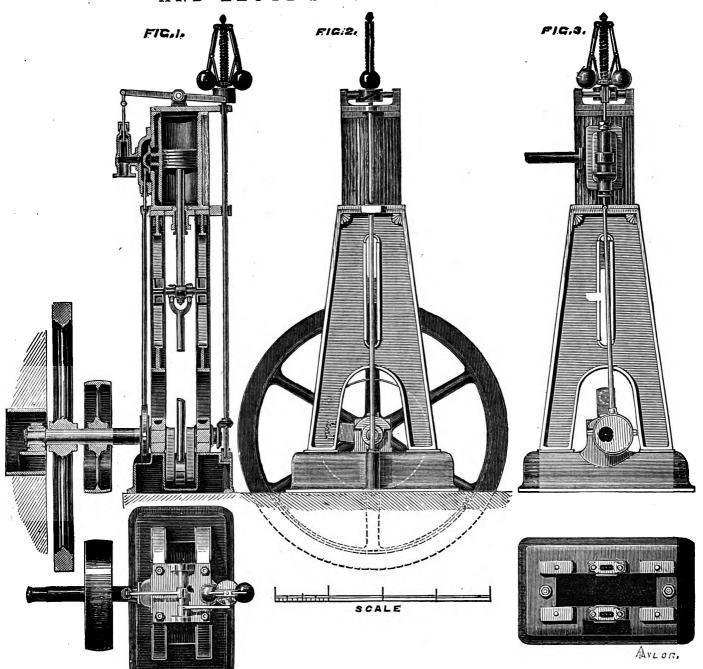

chief cause of dirty plates is perspiration from the hands, and all photographers should be very careful in hot weather to have plenty of plates cleaned early in the morning to last all through the day. When this is not done, and plates have to be hurriedly cleaned in a hot room, many failures will result from the want of a chemically clean surface. He says that it rarely happens that a film splits away from the glass from any fault in the collodion, but most commonly from dampness of the glass before coating. Another great cause, which he does not notice, of the slipping away of pictures from the glass, is the dipping of the plate in the bath too soon after it is covered with the collodion. He says that with "the bromo-iodised collodions now in the market, it is better to have the bath nearer 40 than 30 grains to the ounce. A very weak bath tends to give fog, and even when working mode-rately well, there is a strong tendency to violent contrast. On the other hand, however, with a 40-grain neutral bath, and with a developer of 30 grains, it will be found that if there is a slight over-exposure, or much diffused light in the room, or any stray light in the dark room, or doubtful yellow glass, there will also be fog. A distinct difference in the two kinds of deposit will, however, be visible; the plate from the weak bath will have a coarse, grey, muddy deposit upon the shadows, whilst that of the other will be very white and fine . . . . It should be remembered that the strength of the iron solution materially affects the deposit of silver upon the plate, and that, when great delicacy is required, as in the rendering the details of a white dress, a solution of 10 grains of iron will be found much better than one of 20 grains. The improved result is due to the great clearness of all the shadows. A weak developer will also easier give a brilliant result than a strong one, if the negative be well exposed in a good light." He says, also, that whilst a bath of 30 grains will serve for a collodion giving a thin opal film, not less than 40 grains will do for one of a thick creamy character.

Mr. John Spiller, F.C.S., points out that photographs upon paper, which look cold and flat, in consequence of over toning, can be much improved in appearance by being painted over with a weak solution of red aniline dye. He employs solutions of acetate of rosaniline (magenta), containing one-tenth of a grain or less of the salt, dissolved in a pint of water. Mr. Russell Manners Gordon, a very successful worker in dry plates, communicates a paper upon the gum and gallic acid dry process. He says that, unlike most dry plates, they work well with iron develop-ment. The developer consists of gelatine, 1 grain; acetic acid, 15 minims; photosulphate of iron, 20 to 30 grains; water, 1oz. After wetting the plate with distilled water, previous to development, take as much of the above iron solution as is necessary to cover the surface of the film, and add to each drachm one drop of a 30-grain solution of nitrate of silver. Add the silver to the iron developer before pouring it over the film. The development is nearly as rapid as that of a wet plate. Intensification may be performed by adding a few drops more nitrate of silver to the developer, applying it, and then well washing the plate. Afterwards complete the intensification with pyrogallic acid, 2 grains; citric acid, 2 grains; water, 1oz.; and a few drops of the silver solution.

of the silver solution.

The useful little publication now under notice contains also "A Word on Art in Photography," by M. Adam Solomon; "Rapid Solar Camera Printing," by J. E. ### SIX-HORSE POWER VERTICAL ENGINE AT WISHART AND LLOYD'S TOBACCO WORKS.

#### MACHINERY FOR MANUFACTURING TOBACCO.

OBACCO, in one shape or other, is such a familiar object to all, that few pause to inquire into the manner in which it is converted from the raw leaf into the marketable form. If they did, they would find that it involved some very nicely-adjusted mechanical arrangements, and that in the production of ordinary cut tobaccos, the mechanical engineer plays no mean part. In mechanical engineer plays no mean part. In points about it well worth noticing. It has a one of the engine by bevel wheels at its lower order to place before our readers the mechanical cylinder 8in. diameter and 16in. stroke, end, two strokes of the cut-off valve are

by Samuel Fry. There are also contributions by J. W. Swan, Fred. R. Window, Walter Woodbury, A. de Constant, W. H. Davies, William Blair, Dr. Liesegang, J. R. Johnson, H. Baden Pritchard, William Mayland, George Wardley, Alfred Keene, Netterville Briggs, John Eastham, Peter Mawdesley, F. W. Hart, Matthew Whiting, jun., J. M. Burgess, R. Slingsby, H. Kelsall, M.D., F. G. Eliot, E. Cocking, C. E. Pearce, T. Gulliver, and P. Meagher. trade require it.

Commencing with the motive power, we will descend to the basement, where we find the engine, which forms the subject of the engraving above, and in which fig. 1 is a vertical section and a plan, fig. 2 a side elevation, and fig. 3 an end elevation and plan of the framing. This engine was conplan of the framing. This engine was constructed by Messrs. Kittoe and Brotherhood, of Compton-street, Clerkenwell, having been designed by the junior partner of that firm. It is a 6-horse power vertical engine, and drives the whole of the machinery. It has some

standing on the top of two A-shaped frames which have the guides for the cylinder crosshead cast in them. They are bolted at the bottom to a compact bed plate, having two plummer blocks cast on, carrying a wroughtplummer blocks cast on, carrying a wrought-iron crank close to the throws, an outer bear-ing being provided in a wall box. The slide valve is worked by an eccentric in the ordinarymanner, and cuts off at three-quarters of stroke. There is an automatic expansion or stroke. There is an automatic expansion worked by the governor, as shown in our engraving. A spindle passes from the bed plate to the upper part of the engine, and carries a governor, which acts upon a cylindrical block sliding on the spindle, and having a cam groove cast in it, into which the pad of a love is fitted with a steel roller. having a cam groove cast in it, into which the end of a lever is fitted with a steel roller; a shaft carried in brackets on top of cylinder communicates motion to the cut-off valve, situated at the back of the main valve box. The cut-off valve is a long piston working in a cylinder, steam-tight, and passing in its strokes an annular opening in the cylinder. The governor spindle being driven at two to one of the engine by bevel wheels at its lower and two strokes of the cut-off valve are

Digitized by Google

given to one of the engine, and suppression takes place sooner or later, according to the position and height of the balls of the governor. This is found a very efficient expansion apparatus, and regulates the speed of the engine to a nicety, and an uniform speed of 75 revolutions of the engine is obtained under all conditions of load. The engine, therefore, works with great economy, and uses an exceedingly small quantity of

steam, giving every satisfaction. The steam, after leaving the engine, exhausts into a feed-water heater, which consists of a cast-iron cylinder, about 3ft. high and 2ft. diameter, having a cast-iron pot of somewhat smaller size inserted into it with suitable steam-tight covers, on the top of which one of Kittoe and Brotherhood's patent No. 1 Paragon pumps is fixed, which pumps the feed water into the pot, and thence it finds its way into the boiler through a nonreturn valve. The feed water thus receives a great accession of heat, and enters the boiler almost at 200deg.; and the small donkey engine works admirably with little cost, and, we were told, has given no trouble whatever since it was started. An exhaust pipe leaves the heater and enters the chimney after having done its work. To drive the engine, a 10-horse power Field boiler is used, having a descending flue which passes under the floor, thus occupying no room above its top, which is just under the ground floor, and covered with a grating to admit light and air.

On the basement also is the apparatus for grinding the knives of the tobaccocutting machine, and which consists of two of Ransomes' free grit grindstones, 4ft. 6in. diameter, and 16in. wide, running in a castiron trough, and having a lateral motion imparted to them as they revolve. The knives are fastened in a rest, and kept stationary; the edge being in contact with the stones, a perfectly uniform bevel is obtained, and the knives are ground with great precision. This apparatus was supplied by Messrs. Kittoe

and Brotherhood.

The engine drives a line of shafting in the basement, from which motion is communicated to the various machines there. From this shafting, motion is also transmitted to shafting on the ground floor by means of a belt and riggers. On this floor we found the tobacco-cutting apparatus, which was supplied by Mr. R. Legg, of Owen's-row, St. John's-street-road. This is a selffeeding machine, by which cut tobacco can be manufactured in a much more perfect, expeditious, and economical manner than by the imperfect machinery formerly in use. Previously to the introduction of Mr. Legg's machine in 1859, two separate machines were required for cutting tobacco into fine shreds, called "Shag." First, the press (either screw or hydraulic) in which the leaves were formed into hard cakes; and, second, the cutting-engine, in which the cakes of leaves were cut into shreds. The labour of filling and working the presses and of removing the cakes from the presses to the cutting engine was considerable, and some kinds of tobacco were much deteriorated by Then, the mechanical action of the process. the cutting engine was very faulty, inasmuch as, in it, the cakes of leaves were pressed in a kind of horizontal vice, and afterwards squeezed out from between the two fixed flat surfaces towards the knife, thus producing great strain and friction; besides which, a considerable portion of both ends and sides of each cake, being imperfectly cut, were thrown back as "pickings," and helped to make "smalls" in the next box or cake. Mr. Legg's machine receives the leaf

tobacco into a feeding trough or box, from which it is drawn and pressed by rollers; the which it is drawn and pressed by rollers; the lower roller, of very large diameter, is faced with wood, thus forming a cylindrical chopping block, and on it the knife descends. The upper, or compressing rollers, are smaller, and of metal; they are placed between the conditions of the premises in a very dry and brittle condition, it first undergoes a steaming in a kind of closet full of these, 1,450 were original American works, 359 trays. It is transferred thence to the liquor-ing floor, where it is properly prepared for further operations. That for cavendish and continent of Europe.

feeding box and the knife, and the bearing blocks for their ends are so fitted that they may slide up or down according to the thickness of the feed, and are held down with a yielding pressure obtained by means of weights and levers. All the rollers are made to revolve simultaneously, and with intermit-tent motion, corresponding with the up-strokes of the knife-arm, by means of ratchet wheels, which may be changed at pleasure for others with a different number of teeth, in order to produce the required degree of fineness in the cut. By this combination, all the labour and waste of pressing in a separate press is avoided. Just sufficient pressure only is given to the tobacco to make it firm enough for cutting; consequently, the shag is much brighter and more bulky, it separates more readily, requires less labour, and makes less "shorts" in dressing, and the facility with "shorts" in dressing, and the facility with which all the leaves are laid in and drawn straight forward by the rollers, ensures every cut being made in the right direction, that is, across the leaf. From an inspection of this machine, while at work, we are able to speak to the perfectness of its operation. It is one of Mr. Legg's largest size, and contains all his recent improvements. The bed plate is very massive, whilst the whole of the framework, without being cumbrous, is well adapted to resist the great strains caused by the rapid reciprocating motions of the machine. All the wearing parts have improved means of adjustment, and a great convenience is introduced in the form of wedges, actuated by screws, for gradually raising the main drum as the wood wears away.

On the same floor is placed the steaming apparatus, which consists of a perforated copper cylinder, closed at one end by a movable cover, and caused to rotate alternately in each direction by self-acting gear under the floor. The cylinder is carried on friction rollers in a steam jacket, and steam is admitted, which finds its way through perforations to the tobacco, provision being made to prevent its provision imparting moisture; and when the operation is complete, a plunger is forced forward, and ejects the tobacco on to the stove pan. This stove pan, or hot plate, is simply an open metal trough heated beneath, and is used for the purpose of drying the tobacco when it is ejected from the steaming apparatus. Adjoining this hot plate is a cooler, which is another open trough, having a perforated bottom. On this the tobacco is laid to cool after it has been removed from the hot plate. The cooling is here effected by means of an induced current of air, which is drawn downwards through the tobacco by a passage which communicates with the chimney of the boiler

On the floor over this is a steamer for opening the raw leaf, and a liquoring floor, which is laid with asphalte, and inclines from all sides to a given point, at which the super-fluous liquor flows off. The floor above is the stock room, where all the tobacco is received, and from whence it is issued to the various departments. Mounting still higher, we come to the spinning floor, where the roll tobacco is prepared. Here is a long table and a spinning-wheel, by which the leaf tobacco, properly prepared, is spun into various thicknesses of rope. The rope is then wound into balls or other marketable shapes, and is subjected to great pressure in substantial presses, one of which, of improved form, was supplied by Mr. Legg.

It will thus be seen that the raw tobacco

undergoes various manipulations before it is ready for use. The operations may be briefly summed up as follows, with reference to the machinery already described:—The leaf tobacco being received on the premises in a very dry and brittle condition, it first under-

roll tobacco is sent to the spinning room, that for cut tobacco is sent below cutting machine, which it leaves in very fine shreds, which adhere closely to each other. It is opened in the revolving steamer, dried on the hot plate, and cooled on the cooler close by, which it leaves in a fit state for the market. Messrs. Wishart and Lloyd have evidently spared neither trouble nor expense in rendering their manufactory as complete as possible. The arrangement of all the details is exceedingly satisfactory, and the machinery does credit to the two firms by which it has been supplied.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

WHITE PICKLE FOR ARTICLES OF COPPER AND BRASS -OXYGEN FROM SULPHURIC ACID-A NEW GUN-POWDER—COLOURING MATTER FROM COCKCHAFERS -REMOVAL OF PHOSPHORUS FROM IRON-COPPER

DR HILLER recommends the following as an improved means of giving a silvery lustre to articles of brass and copper. The old process, by the use of cream of tartar and powdered tin, is slow, and gives uncertain results, but the solutions here described by the doctor give very uniform effects in a very few minutes. One part of salts of tin is to be dissolved in ten parts of water, and to this solution (continually stirred) is to be added a second, made by dissolving one part of caustic potash in ten parts of water. The mixture will be cloudy at first, but will gradually become clear, and is then ready for use. Objects to be whitened i.e., tinned, have only to be immersed in the mixture, made hot, a thin plate of tin of considerable surface being immersed at the same time.

A mode of preparing oxygen, which may, under some circumstances, be cheap and convenient, is given by M.M. Clomadeuc and Moret. saturate fragments of pumice stone with sulphuric acid, and heat them in an iron retort. The vapour of sulphuric acid thus obtained is carried into or more other retorts, filled with pieces of pumice and heated to whiteness. The sulphuric acid is thus dissociated, as we say now, into sulphurous acid, which is arrested by water, while the oxygen can be passed on to a gasometer. Thus the manufacture of sulphurous acid with the sulphurous aci facture of sulphurous acid might be combined with the production of oxygen.

A new gunpowder of extraordinary power is said to have been invented by a M. Perthuiset, but we are not yet enlightened as to its composition. Shells loaded with it can be made to burst

at the moment of impact, or after penetration.

We noticed last year that a lubricating and a salad oil had been extracted from cockchafers. We now read that another chemist obtains a beautiful golden yellow colouring matter from

While the discussion on the removal of phosphorus from iron is going on, we may recal to our readers' notice the experiments of M. Caron, who found that phosphates were completely decomposed by fusion with fluoride of calcium, and that at the temperature of cast steel the phosphorus is completely volatilized.

Copper, most of our readers well know, can be procured in a very fine state of division and fit for bronzing by reducing a solution of a salt of copper by boiling it with grape sugar and a caustic alkali. The difficulty they may have found perhaps has been to separate the fine powder from the liquid, for it does not settle well and soon clogs a filter. Stolba now tells us that the filtration is quickly and easily made, if the alkaline solution be just neu-tralized with sulphuric acid. The powder of copper can then be washed with hot water, and must afterwards be quickly dried in a hot place. dry, the powder oxidizes very slowly, and when rubbed gives a brilliant bronze.

#### INSTITUTION OF CIVIL ENGINEERS.

A T a meeting of the Institution of Olvin Engineers held January 26, 1869, Mr. C. H. Gregory, president, in the chair, the paper read was on a description of the new ferry and the new Brighton T a meeting of the Institution of Civil Engineers piers and landing stages, on the river Mersey, near Liverpool, by Mr. Henry Hooper, Assoc. Inst. C.E. The ferry accommodation of the river Mersey

having been briefly noticed, it was stated that in order to provide a means of communication by water between the central and the southern por tions of Liverpool and New Ferry on the opposite shore, the Mersey River Steamboat Company was originated, to run steamers from the Prince's Stage to the south end of the borough, and thence across

to the south end of the the estuary to New Ferry.

This necessitated the erection of a pior, with connecting bridge, at New landing stage and connecting bridge, at New Ferry, which was constructed from the designs of Ferry, which was constructed from the designs of Mr. Brunlees, M. Inst. C.E., by Messrs. W. and J. Galloway and Sons, under the superintendence of the author. The pier consisted of fourteen spans, each 58ft. in the clear. It was formed of three lines of wrought-iron girders, placed 9ft apart from centre to centre, and resting on cast-iron columns. The openings were arranged in from columns. The openings were arranged in three groups,—the first, from the retaining wall towards the river, comprising five bays, then two rows of columns; next, four bays and again two rows of columns; and lastly, five bays, terminated by a platform, 18ft. by 16ft., supported on a cluster of eighteen columns and piles. The girders were each 60ft. in length, 4ft. 9in. in depth, and of the ordinary lattice form, footways of Memel planking being carried on the bottom flanges. The two footways were each 8ft. 4in. in width, and were assigned respectively to the traffic passing in opposite directions. The top member of the girder as composed of two half-round bulb irons, forming, when riveted together through the flanges, a tube of 8in. external diameter. The two outside girders were each calculated to bear a load of 120lb. per superficial foot of platform, and the centre girder was nearly twice the strength of the others. The supporting columns were 12in. external diameter, the metal being in thickness. They were generally cast in lengths of 10ft., and connected together by flange joints, excepting the junction of the columns with the piles, which was of a socket form. The piles were cast in variable lengths, to suit the contour of the ground; they were furnished with one turn of a screw at the bottom, 2ft. 6in. in diameter, the metal being 1 in. in thickness at the root, and the top of each pile was of a plain spigot form. The piles were screwed down to depths of from 6ft. to 10ft. by means of capstans.

The outer edge of the platform at the head of the pier formed a bearing for the movable joint at the upper end of the bridge connecting the pier with the floating stage. This joint allowed a horizontal and vertical motion of the bridge, and consisted of a strong wrought-iron girder, having a radial motion round a steel pin, 4in. in diameter, fixed to part of the framework on the top of the columns. The vertical motion was obtained by means of a hinge under each girder of the bridge, composed of a wrought-iron forging, bolted to a rotating girder, and a steel pin, 21 in. in diameter, passed through it, and the two forged straps riveted round the end of the bridge. The under side of the the end of the bridge. rotating girder immediately beneath these hinges was supplied with two sheaves, or rollers, bearing on segments fixed to the heads of the columns. The bridge was 158ft. in length, and was formed of two bowstring girders, on the lattice principle, 10ft. in depth at the centre, and placed 9ft. 8in These girders were kept in place at the bottom by T-irons, and at the top by an arch of wrought iron. The lower end of the bridge was suspended by chains from a wrought-iron cradle fixed on the floating stage. This was considered necessary, to reduce the strain on the pier and bridge, sary, to reduce the strain on the pier and bridge, caused by the rolling of the stage, and was found to answer very well. The platform of the pier was 12ft. above high water of ordinary spring tides, and 7ft. above an extraordinary tide of 21ft.

The floating stage was 100ft. in length by 22ft. in breadth, tapering for a length of 19ft. to 19ft. in breadth, tapering for a length of 19ft, to 19ft, at each end. A spur, 22ft, by 11ft,, projected at the back under the bridge. The pontoon was 7ft. 3in. in depth, and the sides had a batter inwards of 1ft. It was built of ribs of T-iron, and was divided into five compartments by four water-tight bulkheads. To increase its stiffness, there was a longitudinal bulkhead along the centre of the pontoon, and smaller bulkheads under the cradle supporting the bridge. The deck and appurtenances were of the usual description. The

stage was moored by four chains, two at each end of the pontoon. Each chain was fifty fathoms in length, and at right angles to the adjoining one, the end of each being secured to an anchor with Provision was made for taking in the slack of the chains by two sets of gearing, fixed on the stage, one at each end. The pontoon drew about 2ft. of water, and at low water of spring tides there was never less than from 7ft. to 8ft. of water at the front of the stage.

The dimensions of the various parts of the structure were given in detail; and with regard to the expenditure upon the works, it appeared that the approaches cost £1,063, the pier (including the bridge) £7,740, and the stage £2,674, making a total of £11,477.

The design for the new Brighton pier and landing stage was of a similar character to that of the new Ferry pier, and was likewise furnished by Mr. Brunlees, the original contractors being Messrs. Rothwell and Co., but the works were finally completed by Messrs. Bowdler and Chaffer. The pier consisted of three lines of wrought-iron girders. each 60ft. in length, the number of bays or spans being twelve, divided into three groups of four spans each, by two intermediate rows of columns. The enlarged platform at the river end of the pier was 33ft. 6in. by 16ft., and was supported by short wrought-iron girders, resting upon a cluster of twenty vertical and thirteen raking cast-iron columns, 12in. external diameter, the metal being three-quarters of an inch thick. The screw piles were 2/t. 6in. in diameter, and had a pitch of 7in. three-quarters of an inch thick. They passed through variable depths of from 5ft. to 8ft. of sand and gravel to the surface of the rock underneath. The width of the pier from centre to centre of the outside girders 4in.; the centre girder dividing the platform into two footways, each 10ft. in the clear, the girders forming the parapets. The bridge connecting the pier and stage was 160ft. in length; the two girders The bridge connecting the were 11ft. apart from centre to centre, leaving a clear footway of 10ft. 3in. The upper end of the bridge had a similar motion to, and the lower end was hung by chains from a wrought-iron cradle on the same principle as that at New Ferry.

The floating stage was 200ft. in length by 30ft. in breadth, and consisted of a series of twelve pontoons, connected by three lines of lattice girders and two lines of box keelsons. The end pontoons were pointed so as to act as cutwaters, pontoons were pointed so as to act as cutwaters, and were each 29ft. by 18ft.; the ten intermediate pontoons were 29ft. by 11ft. 6in., and the depth of all the pontoons was 6ft. 8in. The stage was finished in the usual manner, and was provided

with all necessary fittings.

The dimensions of the various parts were given in detail, and in conclusion it was stated that the total cost of the pier, bridge, stage, and subsidiary works had amounted to £23 906.

It was announced that the monthly ballot for members would be taken at the next meeting, Tuesday, February 2, when the following paper would be read—"The Mauritius Railways, Midland Line," by Mr. J. R. Mosse, M. Inst. C.E.

#### THE SOCIETY OF ARTS AND THE PATENT LAWS.

N an exhaustive paper read by Mr. Davenport before the Society of Arts, in which the author gives a history of the Society from the period of its incorporation to the year 1852, the following observations on the Patent Laws occur. They are well worthy of reproduction in our columns, as indicating what the Society of Arts has done to promote the interests of inventors in this direction. Mr. Davenport says:-

I must now travel back to the year 1849, when the Council resolved to appoint a committee to consider and promote, if possible, legislative recognition of the rights of inventors, and in November, 1850, it was announced "That a number of noblemen and gentlemen, members of the Society, have consented to act as a committee for promoting the legislative recognition of the rights of inventors, by means of an easy registration of them in accordance with the principles agreed on by the council in 1849.

These principles were:-"1. That inventors, designers, &c., ought not to be subjected to any other expenses than such as may be absolutely necessary to secure to them the protection of their inventions.

enced in connection with patents should be removed.

designs for articles of manufacture, and the protection afforded to the authors and proprietors of inventions and of designs in arts and manufactures, are inadequate.

"4. That for carrying out these objects, the co-operation of all persons interested therein be invited.

"The points on which the committee wish particularly to obtain information are:—lst, the effect which the existing system of patents may have had in suppressing and thus depriving the public of the knowledge and the use of inventions of those who are unable to bear the heavy expenses required under it. And 2nd, heavy expenses required under it. instances where the expenses have been fruitlessly incurred.

At the first meeting of the committee, held on November 19, 1850, the committee unanimously affirmed the principles on which they were constituted, and resolved to prepare at once the draft of a bill embodying them; and at the second meeting, on November 29, the following resolutions were passed :-

"1. That the present tribunals are insufficient for the trial of subjects of designs and inventions.

"2. That there should be penalties for using the title of patent or registered, where none has ever existed.

"3. That registrations of inventions shall be obtainable for a period of one year, on payment of £5; and shall be renewable for four periods, of five years each, on payment of £10 at first val; of £20 at second renewal; of £50 at third renewal; and of £100 at fourth renewal.

"4. That the surplus profits, after paying office expenses and compensation, shall be directly applied to some public purpose connected with invention, but not carried to the consolidated

The first report of the committee was ordered by the Council to be printed and published on December 2, 1850. It reviewed the position of the inventor in this country. A British subject, it stated, has no right of property whatever in the intellectual labour which produces invention or scientific discovery, excepting such as can be obtained by petition from the Crown.

The inventor in France, in America, in Holland, and in Bolgium, even in Austria and Spain, has his right recognized by declared law, but the Englishman has none.

That England presents the anomaly, that, whilst it is the greatest manufacturing nation in the world, possessing boundless capital and most active industrial energy, combined with a vast amount of inventive ability, to which the genius of the people gives the most practical development, the principles of jurisprudence which should regulate its inventive science and its manufacturing skill are very far behind those of other nations inferior in civilization to itself.

"The committee will proceed to determine those principles which it has appeared to them ought to regulate the jurisprudence of inventions.

"The peculiar circumstances under which inventors are placed will be first examined. be impossible,' as a recent treasury report states, to ascertain with certainty when grants of letters patent for the sole use of inventors were first made in this country. in this country. . . . but the Crown has always been the source of that absolute power which determines rights not otherwise defined, and always possessed the full power of granting letters patent for inventions.'

"It has appeared to the committee unnecessary to show how the exercise of the royal prerogative since the first letters patent were issued in the third year of King John, A.D. 1201, affected those rights which, by the progress of the nation, are no longer subjected to the will either of the Sovereign or of the ministry, which have become the responsible interpretors of it; but it must be noticed that whilst many rights and objects were formerly regulated by the legislature, still the Crown continued to exercise a power of granting all that class of smaller personal rights which were generally designated as monopolies. Even this power of granting monopolies became intelerable, and, in the 21st of James I., it was taken away by Parliament from the Crown. . . . In the famous Act of the 21st of James I., c. 3, the power of granting monopolies was abolished; but the power of granting letters patent for inventions was left.

"2. That the difficulties and anomalies experimed in connection with patents should be removed.

"3. That the present term of copyright in position to claim any right whatever until he has

passed through thirty-five official stages of cost and delay.

The committee then proceed to point out the difficulties by which persons holding patents were surrounded, if circumstances rendered an appeal to law necessary, in order that they might maintain their rights, as well as to the efforts which, during the past twenty years, had been made to amend all experience had proved that it ystem, but was hopeless whilst the present system of granting patents existed.

After an elaborate examination into the various views and opinions as to what constitutes an inven-tion, and the conditions under which inventions should be protected by law, the report concluded as follows:—"It would thus appear that it is simply the business of the State to provide an easy means of registration of claims which the law should regard as valid until they are proved to be otherwise, as it is the case in almost every civilized country but our own. And the establishment of any tribunal to investigate claims either before they are disputed or afterwards, appears altogether a separate and distinct question, quite independent of the policy of recognizing the rights of inventors to the fruits of their labour."

Appended to the report was a comparative view of the laws for the protection of inventions in Europe and America. On January 15, 1851, Mr. Henry Cole, the

chairman of the Council, in his address, said :-

"Already the members of the Society may be congratulated on the successful results of the labours of the influential committee of its members, which has been formed to promote the legisof inventors. lative recognition of the rights has been announced that her Majesty's Govern-ment are prepared to ask Parliament to confer the right on inventors to exhibit their inventions at the Great Exhibition, without subjecting them to the pains and penalties for so doing which are entailed by the present system of patent laws, and there can be little doubt that this right, so consistent with honesty and common sense, will be continued beyond the period of the Exhibition. The labours of the Council will not be relaxed in affording every assistance to invest invention with its due rights and position as a science

A special Act of Parliament was subsequently assed, under which inventions were allowed to be exhibited at the Great Exhibition of 1851, upon registration and open to subsequent patent; and in the second report from the committee, printed January 22, 1851, it is stated that, "in addition to the early results of their labours, the committee have received announcements of the formation of numerous committees established with similar objects of promoting complete reform of the patent These committees have been formed in the metropolis, Manchester, Belfast, Birmingam, Leeds, and other places. They have also had brought to their notice the resolution passed at a meeting of the British Association, by a committee consisting of several of its most distinguished members. Some of the views expressed by these committees are announced in the appendix to the

report."
The resolutions referred to as having been sed at the British Association were as follows:

"I. That the patent laws as they new exist are capable of great improvement.

"That the right of property in invention is entitled to as great a protection as the right of

property in literature and the fine arts.

"3. That it might be expedient to remove the heavy expense now attending the taking out of patents, and adopt a graduated scale for portions of time renewable, and increasing from a lower to a higher rate.

"4. That previous inquiry by a competent tribunal should take place before granting patents." The report of the Society's committee then pro-

The result of the deliberations of the committee has been the production of the following resolutions, which the committee venture to offer to the consideration of Her Majesty's Government, as the basis upon which it appears to them that a reform of the present system should be promoted in Parliament

"1. That everything in respect of which a patent may now be granted should be registered.

"2. That the benefits afforded by registration

should extend to the United Kingdom of Great Britain and Ireland and the Channel Islands.

43. That the registration should be considered erely as a record of claims, and not as any determination of rights between parties.

4. That it should be competent to an inventor

to make disclaimers, and to rectify errors in his specification.

"5. That registration of inventions should be obtainable for a period of one year, on payment of £5, and should be renewable for three periods of five years each, on payment of £10 at first renewal, of £20 at second renewal, of £50 at third renewal, and a fourth renewal should be obtained upon appeal, as at present, to the Privy Council. principle of renewed payments, increasing in amount, is proposed as a means of testing whether an invention is in use, and of removing useless inventive rights that might otherwise be obstructive of improvements.)

"6. That there should be penalties for using the title 'patent' or 'registration' where none has

ever existed.

7. That the present tribunals are insufficient for the trial of subjects of designs and inventions.

"8. That it should be permitted to sommence actions for infringement of the rights of inventions

in the county courts.

"9. That inasmuch as, contrary to expectation, very little litigation has been created by the rights conferred by the Designs Act of 1842 and 1843, the committee is of opinion that a fair trial should be given to the working of the proposed system of registration of inventions, before any special tribunal to determine inventive rights is substituted for existing tribunal

"10. That any tribunal before which proceed-ings are commenced, should have power to refer any case for report and certificate to the registrar,

any case for report and estimate the sur registrat, assisted by competent and estimatific persons.

"II. That upon the illegality of the registration being established by the judgment or order of a competent tribunal, the registration should be cancelled.

"12. That there should be only one of the transaction of business connected with the re-gistration of inventions and the payment of fees thereof.

"13. That every person desiring to register an invention, should submit two copies of the specification of his claim, accompanied in every case, when it is possible, by descriptive drawings.

"14. That the mode and procedure of registration should be regulated by the Board of Trade.

tion should be regulated by the Board of Trade, subject to a report to Parliament. "15. That an annual report of all specifications

registered, with proper indexes and calendars, should be laid before Parliament.

"16. That a collection of all the specifications should be made, calendared, and indexed, and deposited for public information in the British Museum.

"17. That it is highly desirable that s collection should be printed and published.

"18. That the surplus profits, after paying office expenses, should be directly applied to some public purpose connected with invention, but not carried to the consolidated fund.

"19. That the importation of any patented invention practised abreed ought not to confer a title to registration, except in the case of the proprietors and inventors, within twelve months from the date of the foreign patent, and that no invention of which the patent has expired in any foreign country, or which has been published for a period of twelve months in any foreign country, or which is in free public use in any foreign country, eaght to be capable of being registered in the United Kingdom.'

The committee in their report review the objections which have been advanced against the principle of registration and progressive fees. They say:—"The argument that the present great cost of patents, by rendering the rights few, is a benefit the manufacturers, is unsound. test does not determine the merit or legality of the invention, but simply proves that the inventor could either afford to pay the fees, or that he could induce some one else to pay them for him. In short, the very reverse of the inconvenience prophesied may be expected from cheap registra tion of invention. Make little rights respected, and a better tone of morals is fostered towards all rights, both large and small. nize the right of inventors, and invention will be elevated into a science. Those who fear such a result are those who fear the spread of education and are like those who, in the middle ages, would have burned astronomers and metallurgists as witches, and who even within the memory of the

present time denied the pretensions of geology or political economy to the rank of a science."

In December, 1851, upon the opening of the Society's Exhibition of Inventions, the provisional Phill presed by the Government is thus Registration Bill passed by the Government is thus referred to—" The Act of 1851, allowing a pro-

visional registration in the case of inventions exposed at the Great Exhibition, appeared to the Council to be a great public good, and a reform in the direction recommended in their two reports on the rights of inventors, and it was their wish, if possible, that permission should have been given to expose such inventions at the rooms of the Society after the close of the Great Exhibition, without prejudice to their future patentability; and, in other words, that the principle involved in that Act should be confirmed in other cases than the one which originally gave rise to it.

"As the Board of Trade did not see fit to accede

to this request, the present collection has been deprived of a great number of articles of interest

and scientific value.

"It is an evidence of the favour with which the public would receive a cheap patent law, such as that recommended by the Council in their two reports, that although the Act of 1851 only came into operation on April 22, the registrations made under it amount to more than a third of the whole number, otherwise registered and patented during the twelvemenths, ending October 31. Upwards of 700 persons availed themselves of the Act on this occasion, and registered and exhibited their inventions."

The third report of the committee, printed in January, 1852, referred to the attempts made dur-ing the last session of Parliament, and the prospects of the present session in improving the patent law. The Council congratulated the Society that the Act passed before the opening of the Exhibition of the Works of Industry of all Nations recognized the right of property in invention, independently of the payment of any fee, upon disclosing the nature of the invention to the public; the simple registration of the right without any preliminary judgment passed on its novelty or merits; the policy of exhibiting and publishing the invention by which the interests of science, as well as those of the public and proprietors, are rendered reciprocal

The committee state that they had under their consideration the patent bill, which was sent from the Lords to the Commons in the last session of Parliament, and take exception to the creation of a numerous commission of the high officers of state, and other matters in the bill referred to, call attention to the evidence printed in their second report, and add—"With all the experience of the past session, and after the very general discussion the subject which has taken place, the committee see no reason to modify the resolutions by which they sought to establish the fundamental principles of jurisprudence which should govern improved legislation in the recognition of patent rights, and with increased confidence again submit them to the consideration of the Legislature.

The committee prepared the heads of a bill to embody these resolutions, accompanied with an explanation of the mode in which the system was

likely to work.

Bill, embodying in the main the principles laid down by the Society's committee, was soon afterwards passed by Parliament, and it still continues to be the Patent Law of England. Under it the people of this country have obtained protection at small cost, immediate publication of the specifications, a patent library of reference, and a museum of patents for consultation. This museum is arranged in a temporary building placed on the ground, bought by the commissioners of the Exhibition of 1851.

#### INSTITUTION OF NAVAL ARCHITECTS.

WE have to inform our readers that the tenth annual meeting of the Institution of Naval Architects will take place on Thursday, Friday, and Saturday, the 18th, 19th, and 20th of March next, at the Hall of the Society of Arta, John-street, Adelphi, Londou; morning meetings at 12, and evening meetings at 7, as usual. Papers on the principles of naval construction; on practical shipbuilding; on steam navigation; on the equipment and management of ships for merchandize and for war, will be read. Gentlemen who propose to read papers should send immediate notice of the subject rar, will be read. Gentlemen who propose to read apers should send immediate notice of the subject papers should send immediate notice of the subject and title of the paper to the secretary at the offices of the Institute, 9, Adelphi-terrace, London; the paper itself, with illustrative drawings, is to be deposited at the offices of the Institution, on or before the 18th of February next. Candidates for admission as members, or as associates, should send in their applications on or before the 1st of March

THE manufacture of postage stamps assumes larger proportions every year; during 1868, 500 millions were produced.

SWING BRIDGE OVER THE CALEDONIAN CANAL.

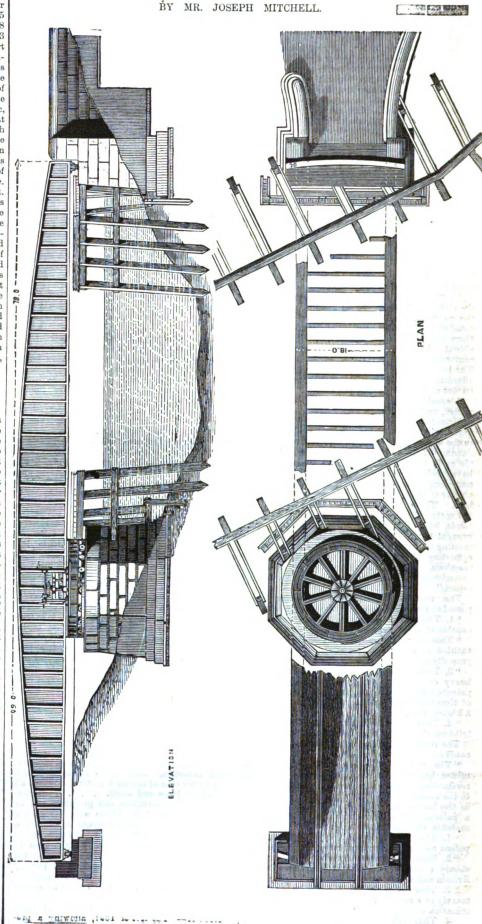

THE Highland Railway works consist of a main line from a point near Perth, extending northward 117 miles to the town of Forres, and a base line running nearly at right angles to the other, extending westward from the town of Keith by Elgin and Forres, along the shores of the Moray Frith to Inverness, and thence along the Beauly, Dingwall and Dornoch Friths, northwards to Bonar Bridge, measuring from Keith to Inverness 55 miles, and from Inverness to Bonar Bridge 58 miles, and making together a base line of 113 miles. These railways traverse the northern part of Perthshire, and are the main lines of communication through part of Banffshire and the counties of Inverness, Nairn, Moray and Ross, the whole including three branches, two to the ports of Burghead and Findhorn, in Morayshire, and the other to the village of Aberfeldy, in Perthshire, xtending to 245 miles in length. The railway at one point crosses the Caledonian Canal, over which t is carried by the swing bridge illustrated in the iannexed engraving, where the structure is seen in elevation, plan, and transverse section. It was designed by Mr. Joseph Mitchell, the engineer of the line, and is a good example of a swing bridge. It consists of two girders of 126ft. in length, 78ft. of which, from the centre of the turntable, spans the canal, and the remaining 48ft. forms the balance weight. Advantage was taken of the canal being emptied for repairs to lay the foundations of the masonry, which are on a platform and piles in the solid gravel, 9ft. below the surface of the water. The depth of the canal is 18ft., and the width of the lock is 40ft., the canal banks being 120ft. apart. Some difficulty occurred at first during hot weather from the expansion of the iron affecting the adjustment of the bridge, which was remedied by means of a powerful screw, and the bridge has been worked with satisfaction and safety for the last five years. This bridge, with its machinery, timber wharves for protection from vessels, distant and station signals, &c., complete, cost

## HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND.

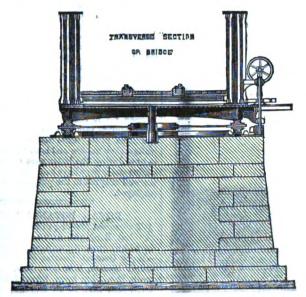

ON Wednesday week a general meeting of this Society was held in Edinburgh; the Duke of Buceleuch, president, in the chair. On the motion of the chairman, the Marquis of Tweeddale was elected president for the ensuing year; and the Earl of Southesk, the Earl of Kintore, the Earl of Dalkeith, and the Right Hon. R. C. Nisbet Hamilton were elected vice-presidents. The other office-bearers having been appointed, Sir William Gibson Craig moved a vote of thanks to the Duke of Buccleuch for his services to the Society while president. Sir William Stirling-Maxwell seconded the motion, which was cordially agreed to. His Grace, in acknowledging the compliment, said that during the three years he had held the office of president, 313 new members had been added, and there had been an addition of £4,862 made to the vested had been an addition of £4,862 made to the vested capital of the Society. Among the new members admitted on the occasion were the Marquis of Queensbury, the Marquis of Bute, the Earl of Perth, and Lord Schomberg Kerr. Mr. Kinloch, jun., of Gilmerton, reported that the show held at Aberdeen last year, although a successful one, had cost the Society something like £450. He stated that the arrangements for the general show, to be held at Edinburgh this year, were in a satisto be held at Edinburgh this year, were in a satisfactory state of advancement. The prizes offered amounted to nearly £1,500, irrespective of the value of the medals which might be awarded for extra stock, and for the first prize animals at former shows. It was arranged that the show should be held on the 28th, 29th, and 30th of July. In regard to the show of 1870, it was reported that a requisition had been received from the Dumfries district, asking the directors to hold the show for that year in Dumfries. It was agreed to comply with the request, and to make arrangements accord-ingly. Mr. Campbell Swinton, of Kimmerghame, reported that during the past year local shows of stock for premiums given by the Society had been held in fourteen districts, and that a sum of about £250 had been awarded, besides a number of medals.

The number of lime kilns in Italy in 1867 was 4,971, and produced 5,799,383 metric quintals of lime, of the value of 11,557,200 francs. The kilns for burning chalk for agricultural purposes were 891, and produced 1,080,372 quintals, of the value of 1,603,670 irancs.

# SWING BRIDGE OVER THE CALEDONIAN CANAL-HIGHLAND RAILWAY.

### SWING BRIDGE OVER THE CALEDONIAN CANAL-HIGHLAND RAILWAY.

#### REMARKS ON WAR ROCKETS. BY MR. J. B. DANCER, F.R.A.S.\*

T the last meeting of the Society a communication from Mr. J. Nasmyth was read on rockets. I was not present at the meeting, war rockets. but have read the paper, and I propose to make a few remarks on the subject of his paper, and to suggest some other method for obtaining similar

Rockets have been employed in warfare from a very early period. They were used by the Chinese in their wars with the Tartars in the thirteenth century; by the Venetians in 1380; and by the French in 1449. They were also employed against our troops by Tippeo Saib at the siege of Seringapatam. The merit of the introduction of this amongst our engines of war is due to Sir William Congreve, who in 1804 very materially improved the rocket for purposes of war, by making them of large size and giving them a greatly extended range, averaging 3,000 yards. greatly extended range, averaging 3,000 yards. Since that time Congreve's name has generally been connected with the war rocket. He had a very high epinion of the importance of these very night opinion of the importance of these projectiles, and thought that rockets from half a ten to a ten in weight might be employed in reducing fortresses. Their efficiency in our hands has been very recently shown against King Theodore's troops at Magdala. It does appear strange that a weapon which combines so many desirable qualifications should be so long neglected. whilst guns, which are so much more cumbrous and expensive, should receive so much attention.

want of precision in the flight of the rocket has doubtless been one reason which has prevented it from being employed more extensively. This deficiency has been in some degree removed by the improvements introduced by Mr. Hale, who suggested that a number of oblique perforations should be made near the nesk of the rocket, through which the ignited composition could escape, and thus impart a rotary motion to the tube of the rocket.

Mr. Hale, who suggested by Mr. Hale, who suggested that a number of oblique perforations should be made near the nesk of the rocket, who was a suggested that a number of oblique perforations should be made near the nesk of the rocket, through which the ignited composition could escape, and thus impart a rotary motion to the tube of the rocket.

Mr. Nasmyth's ingenious contrivance for effecting the rotation of the rocket from the commencement of its flight would doubtless be a very great improvement, but there are certain considerations connected with the efficient employment of rockets which render it very undesirable that that branch of the service should be encumbered with any apparatus, especially mechanism, which could be easily rendered useless by accident or design; and to protect the wheelwork from rifle bullets by iron casings would render the apparatus too weighty for active warfare. At present, rockets are a light and simple artillery which can be rapidly manœuvred; they are not liable to derangement of parts, and they afford a small target for the enemy's riflemen.

The question which occurred to me whilst reading Mr. Nasmyth's communication was this—

. Manchester Literary and Philosophical Society.

Is there any mode of imparting precision of flight to a rocket without adding any machinery liable to derangement or materially increasing the weight of the present apparatus. The first scheme which suggested itself was to replace the present V-rest with a long rifled tube, and to enable this tube to impart the rotary motion to the rocket case, it would be necessary to rifle the outside of the rocket case to correspond. This could be added in several ways to the present cases. One method, which would be expensive in degree, would be to force the rocket case into a rifled sheet iron tube—these tubes could be easily made of thin sheet metal in a draw bench, on a rifled mandril, by means well known to mechanicians. In this way we should have a rifled rocket case which would receive a rotary motion at the commencement of its flight from the rest. If the friction caused by its flight from the rest. If the friction caused by the rifling proved objectionable, possibly by closing the end of the tube rest an additional impetus at the commencement of the flight of the rocket would be obtained. A small charge of gunpowder, or preferably one of gun cotton, placed at the end of the rocket composition during the manufacture, might be the best method of overcoming the

A new form of rocket stand would unfortunately be required under these new conditions. If rifled rockets proved a success, it would be easy to give the cases the proper rifling to commence with. As I have before stated, iron tubes of the desired strength according to size of rocket, could be drawn on rifled mandrils. I should prefer that the rifling of the cutside and inside of the cases should correspond, and should expect that the issue of the ignited composition through the rifled interior, would materially assist in continuing the rotation after the rocket had left the rest, acting in the same manner as Mr. Hale's oblique orifices. Considerable accuracy of aim might be obtained without rifling the rocket case. If we wish to give an arrow precision of flight, we affix feathers to one and of the shaft to act as rudders, reathers to one end of the shart to act as rudders, and if these feathers are placed exactly in a line with the shaft, we have directive power without rotation. I would therefore propose experiments to be made by attaching thin metal feathers to the rocket case; these could be attached to the rockets now in use by crimping up, or corrugating thin sheet metal into feathers, or rudders, and forming them into a tube, which could be forced on to the them into a tube, which could be forced on to the them into a tube, which could be forced on to the rocket cases; for those rockets intended to ricochet or for low angles, perhaps, three guides would be quite sufficient, having none at the under side of the case, because they might be knocked off at the first graze, and only tend to deflect the rocket from its intended destination; those for great elevations and long range might be surrounded with a considerable number of feathers, each of small superficial area, to reduce the deflecting power of the wind at great elevations to a minimum. a minimum.

Rocket cases of sheet metal could be so formed the feathers would have the appearance of star-like radiations, the inside corresponding to fire.

the outside. In rockets thus formed the issue of the gases would be in a straight line, and would assist the directive power of the external feathers. Of course, the oblique orifices used by Mr. Hale would not be required in these rockets. The rammers for the composition would have to be adapted to this new form, and the usual V-rest would require one or more parallel guides for the feathers. I should expect feathered rockets to obtain a longer range than rifled ones, and the apparatus would not of necessity require to be more cumbrous than those in present use. I do not profess to have made a study of the subject, therefore, feel it necessary to apologize for taking up your time with suggestions in which I may have been anticipated; but up to the present moment they appear to me to be novel; how far they may be practically useful, I must leave to experimental artillerists to decide.

#### BERTRAM'S PETROLEUM STORE.

MR. BERTRAM, whose safety petroleum store was described and illustrated in the MECHANICS' MAGAZINE, for October 2, 1868, has received a letter from the Metropolitan Board of Works, in which states, that upon examination of the apparatus, it has been considered a safe means of storing this dangerous oil. The Board have re-ferred to it in a circular, which they have drawn up with reference to the operation of the Petroleum Act, and which they have issued to the oil trade. In referring to the various methods of storing, the circular expressly states that the storage "may be effected by an apparatus in which the contents are protected from exposure, and measured in certain quantities on discharge. The specific gravity may also be indicated, and thereby the dealer can ascertain that the oil is of standard quality or otherwise." This special reference to Mr. Bertram's apparatus, and the expressions of the Board on the letter, to which we have referred, are highly gratifying, and must, we are sure, promote the interests of this enterprising inventor.

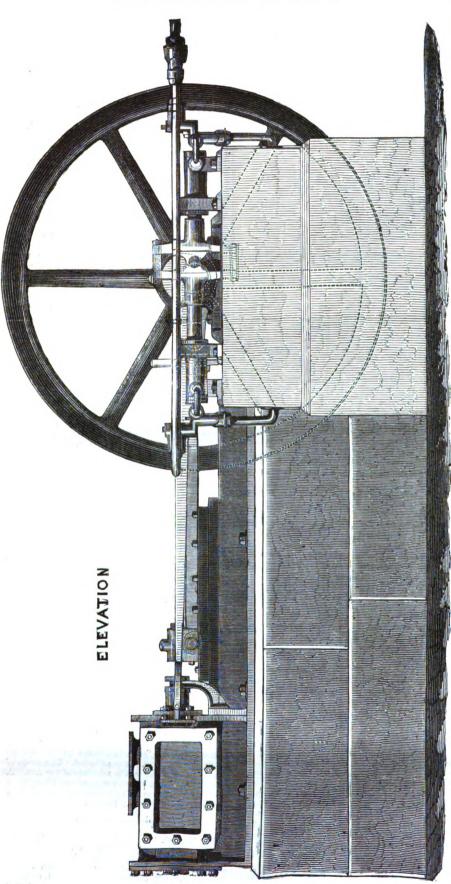

In the interest of many of our readers who are

interested in the storage of petroleum, we append an abstract of the Act with reference thereto, which was passed in July last, and which will take effect on Monday next. This statute is to be construed with the 25th and 26th Victoria, cap. 66. From and after the 1st proximo no petroleum is to be kept, otherwise than for private use, within 50 yards of a dwelling-house er of a building in which goods are stored, except in pursuance of a licence given in accordance with the Petroleum Act, 1862. There may be annexed to any such licence such conditions as to the mode of storage, as to the nature of the goods with which petroleum may be stored, as to the testing such petroleum from time to time, and generally as to the keeping of petroleum as may seem expedient to the local authority. Any petro-leum kept in contravention of the provision is to be forfeited, and, in addition, the occupier of the place is to be liable to a penalty not exceeding £20 for each day during which it is kept in contravention of the Acts of 1862 and 1868. There is a section as to the sale of petroleum for the purpose of illumination. "No person shall sell or expose for sale or use within the United Kingdom, any petroleum from and after February 1, 1869, which gives off an inflammable vapour at a temperature of less than 100deg. Fah., unless the bottle or vessel containing such petroleum have attached thereto a label in legible characters, stating as follows:— Great care must be taken in bringing any light near to the contents of this vessel, as they give off near to the contents of this vessel, as they give off an inflammable vapour at a temperature of less than 100deg. Fah.' Any person acting in contra-vention of this section shall for each offence be subjected to a penalty not exceeding £5." In-spectors of weights and measures are empowered to test petroleum, and offences are to be tried by magistrates, and penalties enforced. The mode of testing is set forth in the schedule of the Act. A definition is given of petroleum, of any bituminous substance that fires off an inflammable vapour at a temperature of less than 100deg. Fah.

On the 11th inst., an accident occurred on the railway running from Pittsburg to Wheeling, about three miles from Pittsburg. A freshet washed away a portion of an embankment; a train ran off the line; a "sleeping car" rolled down a 60ft. embankment, and out of the seven persons it contained three were instantly killed, and the others injured, two of them mortally. As usual, the wreck caught fire.

## HORIZONTAL ENGINE AND PATENT PUMPA COTTON PACKING PRESSES.

BY MESSRS. ROBINSON AND COTTAM.

#### COTTON PRESS ENGINE.

THE accompanying engravings illustrate a horizontal engine and double-acting pump, which are the patented inventions of Messrs. Robinson and Cottam, engineers of the Battersea Works, and by whom they are manufactured. The machines are used in conjunction with a special form of cotton press, of which this firm are also the manufacturers. The engine is of 20-horse power, and the pumps are arranged at each side, as shown in the plan. The pumps are driven by slotted crossheads, in which the cranks on the ends of the flywheel shaft work. The pumps are double-acting, and are peculiarly constructed, one plunger working within the other. The cotton press is constructed on the same principle, and the advantages claimed for it consist principally in giving an extraordinary rapidity of ascent to the ram of the hydraulic press while the cotton is still loose, while a slow motion and heavy pressure is brought to bear during the latter part of the stroke. The engine and pumps have been carefully designed, and are well adapted to the purpose for which they are employed. employed.

ROYAL BOTANIC SOCIETY.

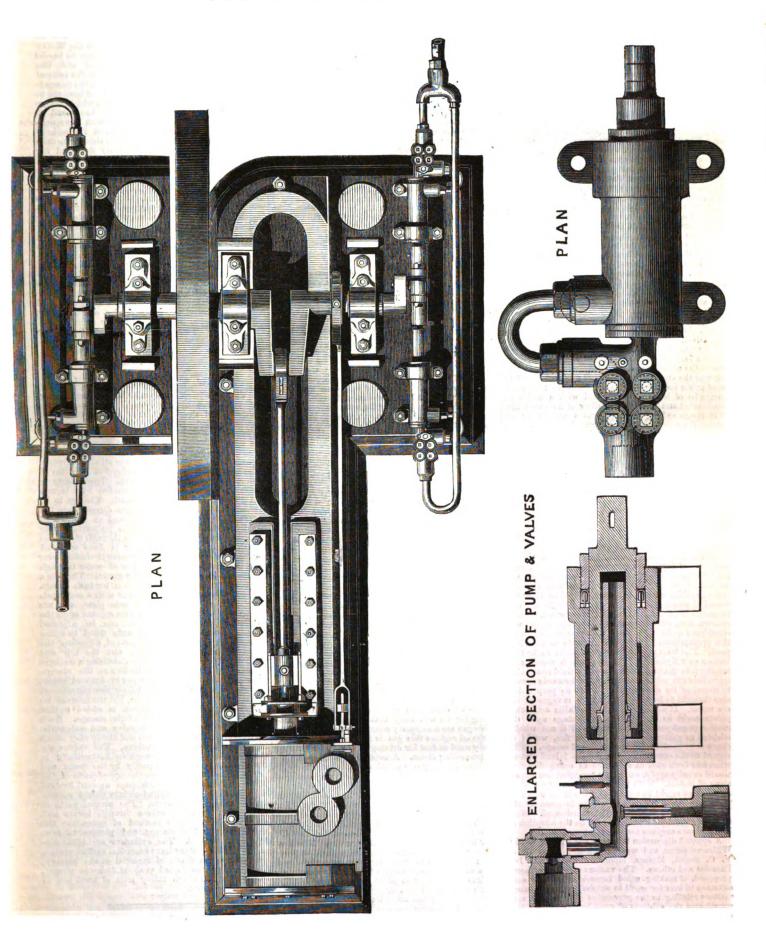

ROYAL BOTANIC SOCIETY.

A Ta general meeting of this Society on Saturday
A last, Benjamin Attwood, Esq., in the chair,
the following were nominated and elected Fellows:
—Major General Charles Stewart, C.B., Captain
Robert Mather, Mrs. Low, Mrs. Webbe, Emanuel
Green, Esq., Mrs. Leon, Edward Hicks, Esq., Mrs.
Bevir, Mrs. Birt, E. H. Brydges Willyams, Esq.,
M.P., Colonel the Hon. Hedworth Jolliffe, Colonel
Alexander Robert Manson, Preston Karslake,
Esq., G. J. Symons, Esq. A curious sample of a
lady's bonnet was exhibited to the meeting by the
assistant secretary, Mr. W. Sowerby. It has just
come from Jamaica, and is said to be made of the
skin of the leaf of a plant. Mr. Sowerby had skin of the leaf of a plant. Mr. Sowerby had examined the substance microscopically, and it agreed in structure with the cuticle of the Yucca, and would most probably prove to be derived from a species of that plant. The material is exceed-ingly pretty and delicate, but not being of a fibrous ingly pretty and delicate, but not being of a fibrous texture is very fragile, and scarcely strong enough for manufacture; the ingenuity of the milliner may, however, invent some plan for "making it up," if the material should ever come into the market. The specimen is placed in the museum, where, although from its antique cut, it may not be very attractive as a fashionable shape, it is none the less valuable as an additional illustration of vegetable substances that are, or might be, used in the arts and manufactures. The museum is found very useful by medical and other students and artists, more especially as the plants from which the various substances are derived, are, as far as possible, cultivated in the department of the far as possible, cultivated in the department of the garden connected with it.

AMERICAN SHIPPING RETURNS.

THE Treasury Department of the United States
Government has published, as a supplement
to Secretary M'Culloch's annual report, a small
pamphlet of important statistics on the tonnage
of the United States, accompanied with a paper
by Mr. Nimmo on the shipbuilding of the Union
from 1817, to 1868, shoring the transfer of 1868. of the United States, accompanied with a paper by Mr. Nimmo on the shipbuilding of the Union from 1817 to 1868, showing a tonnage in 1868 but little more than half what it was in 1855, and very little above what it was in 1847. On June 30, 1868, the total tonnage of the United States, including steam and sailing vessels, barges, and canal boats, we are told, was as follows:—On the Atlantic and Gulf coasts, 2,974,975 tons; Pacific coast, 166,512 tons; northern lakes, 695,604 tons; Western rivers, 581,217 tons; making a total of 4,318,309 tons. The number of vessels which return this tonnage consisted of 18,189 sailing vessels, 3,619 steam vessels, 1,631 barges, 4,679 canal boats; making a total of 28,118. The tonnage in June, 1861, was 5,539,812; in June, 1868, only 4,318,309; a decrease of 1,221,503 tons. In the fiscal year 1854-55, the most prosperous year in shipbuilding, 373 ships and barks were built; in 1867-68 only 69. Mr. Nimmo, showing the falling off in the building of large vessels since the war, says:—"During the five years from 1853 to 1858 65 per cent. of our seagoing tonnage built on the coast consisted of ships and barks, while during the five years from 1863 to 1868 only 28 per cent. consisted of ships and barks, while during the five years from 1863 to 1868 only 28 per cent. consisted of ships and barks; From 1852 to 1862, the aggregate tonnage of American vessels entered at seaports of the United States was more than double that of foreign vessels; from 1863 to 1868, instead of being double, it has declined till it has come to be only 26 per cent. The steam marine gives even more marked returns. till it has come to be only 26 per cent. The steam marine gives even more marked returns.

HORIZONTAL ENGINE AND PATENT PUMP FOR COTTON PACKING PRESSES.

THE CAUSES AND PREVENTION OF MARINE DISASTERS.

THE regular semi-monthly meeting of the New York Society of Practical Engineering was held ■ York Society of Practical Engineering was held at the Cooper Union Building, on Tuesday evening, December 22, 1868, the president, James A. Whitney, presiding. The regular paper of the evening was upon the causes and prevention of marine disasters, and was prepared by Mr. C. Williams, C.E. The subject was treated at length, and several new devices, in addition to those now in use, for the prevention of disasters and for the rescue of wrecked massengers, were suggested and discussed. It was passengers, were suggested and discussed. It was asserted that the greatest and most useful dis-coveries and inventions were those that were intended to secure the most rapid intercommunication between nations and sections of a country, but it could not be said that these improvements embodied the means of safety, as the latter had not probably met with the same encouragement as the desire for rapid travelling. The principal causes of disasters upon the ocean were from foundering, going ashore in storms, gales, or from followering, going asnow in storms, gales, or from false reckoning, the effects of ocean currents, and the destruction of vessels by fire. The causes of disasters upon inland waters, were snagging, burning, and explosions of boilers, The means of safety in case of danger from founder-The means of safety in case of danger from foundering were regarded as being embraced in a vessel so constructed as to secure flotation at a certain depth of immersion, which could be secured by water-tight compartments. It was proposed to attach storm proofs to vessels in such a way that they could be launched or cut loose from the vessel when required. This storm proof could be made of rubber or some analogous substance, and kept distended by iron ribs. A circular shape was thought the best for striking the shore, although they might be made analogous substance, and kept distended by iron ribs. A circular shape was thought the best for striking the shore, although they might be made like a boat, if means could be found to control their direction. It would not require a large one to carry as many passengers as a lifeboat. It was suggested that this plan would also convert the vessel into a life raft, and after a storm had abated, the damages might be repaired, the vessel cleared of water and taken into port, or if not, the passengers could be sustained and sheltered until picked up or land could be reached. In ease of the wreck of a vessel by going ashore, the storm proof, also being surf proof, would afford means for the passengers reaching land. One of the auxiliaries for the prevention of foundering was the steam pump, and this was considered to be of prime importance. It is desirable that such pumps be of large capacity, and with a boiler so constructed and located as to allow of no possibility of stoppage so long as there was a probability of saving the vessel. It was advocated that all vessels above a certain tonnage, should by law be compelled to carry such pumps. In considering disasters by going ashore, the various causes were referred to, such as storms and gales, errors of reckoning, effects of currents, mistakes in soundings, &c. Asto errors of reckoning, if some inuroved means could be of currents, mistakes in soundings, &c. Asto errors of reckoning, if some improved means could be devised for accurately determining the position of the wave by dead are known by the more recommendation. the vessel by dead reckoning, by arriving with more accuracy at the course and distance sailed, the amount of leeway and the effect of the currents, they would be of untold advantage to the navigator. I is also desirable, and thought not to be impracticable, of obtaining some means of almost instant soundings at all times, and to give an alarm when a certain minimum of depth of water was reached. In conminimum of depth of water was reached. In considering the means of preventing disasters at sea and on inland waters, the steam pump was thought indispensable, as it could be employed to clear the indispensable, as it could be employed to clear the vessel of water, and also to extinguish fires. The preparation of the timbers and woodwork, during construction, with some fire-proof preparation, was considered quite possible and not expensive, after the preparations for it had been made at the ship-yard. The least expensive was thought to be that known as "Kyanizing" process, which consists in forcing into the pores of the wood a fluid containing ingredients in solution, which are afterwards turned to stone, or its equivalent. Wood so prepared is also thought to be proof against the ravages of the sea worm. It was thought that metallic and other sea worm. It was thought that metallic and other paints could be employed to advantage upon the most exposed parts of steamers and if not wholly most exposed parts of steamers and if not wholly adapted to prevent the progress of fire, would so check it as to allow of some means of escape. With regard to the causes of disaster upon inland waters, what had been said in reference to ocean disasters would equally apply, excepting snagging and explo-sions of boilers. With the former the danger is not would equally apply, excepting snagging and explosions of boilers. With the former the danger is not so great as might be expected, when it is borne in mind the great number of snags in some of the Western rivers, especially the Mississippi. With the latter the best remedy would be the adoption of low pressure engines for all passenger boats.

A spirited discussion followed the reading of Mr. William's result was a superconstituted in the control of th

A spirited discussion followed the reading of Mr. Williams' paper, and was participated in by Dr. J. V. C. Smith, Messrs. Holms, A. W. Hall, Dr. Pamelee and others. The various methods hitherto proposed, of making wood incombustible, the substitution of iron for wood in shipbuilding, and other matters relating to the prevention of disaster at sea, constituted the subjects of consideration until a late hour, when the Society adjourned for two weeks. At the next meeting the subject of concrete for building purposes will be taken up.—"American Railway Times."

NATURAL GAS.

WHAT the interior of this globe of ours hold, whether it is a solid, a void or vacuum, or a seething mass of molten rocks, a globe of liquid fire, we do not really know. The phenomena of earth-quakes, volcanoes, boiling springs, &c.; the increasing heat as the earth is penetrated; the fact that the temperature is greater at the surface of the earth, or the sea level, than above it, and the escape of inflammable gas from artesian wells, seem to point to an internal inferno of iron. Centuries ago these phenomena were noticed, and their existence used as an evidence of a hell, the locality of which was the centre of the parth. Still, no one of these, nor all taken together, is absolute proof of an incandescent interior. We have never yet penetrated the crust of the globe, nor even probed the crater of a volcano and reached the great internal cavity. If the crust is, as has been estimated, about thirty miles thick, the amount of force necessary to raise the tons of liquid lava to the orifice of a mountain is simply inconceivable, and its effect on the surrounding walls and the surface would be sufficient to materially change the physical characteristics of the country for hundreds of miles around. So, if the earthquake receives its impetus of motion and its almost incalculable power from the agitation of an internal sea of liquid igneous matter, confined within a crust of thirty miles in thickness, and the throes of this sea are transmitted and communicated through this mass to the surface, would the most disastrous carthquake known to history or tradition be sufficient to account for the exercise of such a power? The force that could be sufficient to turn our continents into bottomless seas and our oceans into mountainous deserts. At most, we have a shaking of the surface, a superficial disturbance of the ocean; but no disappearance of the sea through some cavity reaching the molten centre of the globe, and no vomiting forth of a consequent mass of steam, vapour, and lava sufficient to destroy all animal life, and

volcanoes and earthquakes may be accounted for without descending to so great a depth. If the earth's crust is thirty miles thick, there is ample room for the reservoirs of all the power-generating materials necessary for the production of eruptions and earthquakes. That this crust is not solid or homogeneous is not only proved by theories based on analogous truths, but is actually demonstrated by mining, well boring, and the existence of immense caverns, with plains, and hills, and lakes—a subterranean landscape. The increasing heat of the earth below the surface on more demands a vast internal furnace for its existence than does the superior temperature at the earth's surface over the inferior temperature of the call his or the mountain tops. Both may be assigned to the same, or a similar cause, that of weight or pressure, or both combined. What other occult or unknown causes, as electricity, magnetism, galvanic agencies, the nature of which we do not understand, it is immaterial now to enquire. Suffice it to say, that we know that the earth's crust (to use a familiar term without assenting to the theory of the believers in the igneous philosophy) is not solid, and that it contains explosive and inflammable gases which may be sufficient in quantity and powerful enough in explosive and dangerous quality to produce all the phenomena of volcanic cruptions and earth shakings. The difficulty of accounting for the extended character of these latter phenomena—earthquakes—is no greater than if the theory of an internal globe of liquid fire be accepted, as is evident by the statements made by the supporters of that theory of the thickness of the earth's crust.

theory of the thickness of the earth's crust.

That the earth (not merely its interior, but the crust of the globe) is a gasholder, it would be nonsensical to deny. All our coal, whether bituminous or anthracite, contains inflammable gases; coal mines are infested with it, and many of the delvers in their depths annually lose their lives by its explosion, either from accidental causes or spontaneous ignition. No one who is at all acquainted with the business of boring for oil will deny that emissions of inflammable gas are a necessary concomitant to well boring. In the oil regions this gas is frequently and extensively used as fuel for driving the engines, or rather for generating steam. A notable instance is one we mentioned twenty-one months ago, where we spoke of a large manufactory in Erie, the machinery of which was driven and the buildings lighted by the gas from an unproductive oil well. The establishment is that of H. Jarecki and Co., brass workers. For more than two years they have led gas by means of a 3-inch iron pipe from an unsuccessful oilwell 1.200ft. distant from the manufactory, and used it as fuel for their boilers and as light for their works. The flow is never stopped, never changed in amount of pressure; the gas is of good lighting properties, and when at night or on Sundays the works are stopped, the gas still comes; at night being lighted at the mouth of a pipe of 2in. or 24in. diameter, situated near the top of the main building. This light is sufficient to illuminate several streets and squares in every direction, and the escaping gas makes a noise as of escaping steam, that may be heard at a long distance, while the gas flame is not less than 4ft. or 5ft. high.—" Scientific American."

THE MILITARY ARM OF THE FUTURE.

RE long, the Small Arms Sub-committee which has sat at Woolwich, for three years, engaged in determining what shall be the future weapon of the British soldier, will bring to a close its lingering and costly experiments. The sub-committee—on which the country has spent more than £10,000 during the term of its existence—has most rigidly and carefully tested the nine patterns of breechloading rifle submitted to it; and it has been for some time understood that all the other arms have been practically set aside in favour of the Henry and Martini rifles. As yet, however, there has been no decision on the important point, whether the Henry shall be accepted in its entirety, or whether its barrel alone shall be accepted, and combined with the Martini breech. We sincerely trust, for the sake at once of efficiency and of justice between the competing inventors, that the committee will not he sitate to adopt, frankly and entirely, the weapon which, above all other rivals among small arms, has stood so many, so various, and severe tests, both in experiment and in actual use, with the most triumphant results. We do not now need to tell those who take an interest in small arms, whether designed for sportsmen or for our soldiery, that the Henry weapon is an approved and unnistakeable success—not the breech, and not the barrel, but the whole gun. On the other hand, the Martini is only, as yet, an experiment, which a long time and great trouble might be spent in recommending to the public mind. To combine the two systems therefore, would be totake away so much certain and guaranteed good from the Henry system, and substitute so much uncertainty and chance of inefficiency—not to speak of the public disattisfaction that would be caused by any prejudicial compromise. If it be true, as we know good judges say, that to unite the Henry barrel and the Martini breech would give a weapon inferior to the Henry in its entirety, the authorities have slender room for hesitation. It would be a sorry mode of signalizing the commencement of

#### A NEW STEAM STAMP MILL.

A VERY efficient stamp mill is at present being introduced by the New York Steam Engine Company, and those who have adopted it express themselves thoroughly satisfied with its operation. An excellent illustrated description of the machine has been published in a recent number of the "American Journal of Mining," from which it appears that the stamps which are attached directly to steam piston rods are arranged in a group of four, and surrounded by a screen. The battery in which the stamps work is surrounded by a trough cast in the bedplate of the mill. The ore to be crushed is fed through a hopper directly into the centre of the group of stamps, and so distributed equally to all, and as fast as it is pulverized finely enough it is delivered on all sides through the screen into the trough. The stamping is done wet, and the very finest portion of the powder is washed over from the trough by the overflow of water through spouts into an outer surrounding gutter. There is a separate steam cylinder and piston for each stamp. The cylinders are all cast together with a surrounding exhaust steam jacket, and sole plate, and are supported on wrought-iron pillars erected upon the bedplate. All the cylinders can be adjusted simultaneously by means of nuts fitted to screw threads on pillars, for the purpose of adjusting the clearance between the piston and the top and bottom of the cylinder, and for maintaining a uniform clearance by lowering the cylinders as the stamps wear away and allow the pistons to descend lower. The steam acts above and below the pistons, so that it not only lifts the stamps, but the force of its downward pressure on the piston is added to that due to the weight and fall of the stamps. Each cylinder has an independent valve and automatic valve gear, so that each piston and stamp may work independently of all the others. The valves are short double-faced slides, working horizontally in the chests, and operated partly by the steam and partly by conical surfaces on the upper parts of the piston and stamp

A FINE specimen of the white-tailed eagle was shot in the park here (Chilham, Kent), on the 11th inst.; a male bird, weighing over 9lb., and measuring 7ft. 6in. from wing to wing.

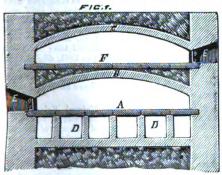

CALCINING FURNACES.

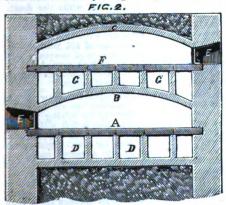

THE ordinary method of heating a close furnace is by passing the flame between the two arches at the top, and then once or oftener under the tiles which form the bottom of the furnace. The invention we are about to describe, and which has been patented by Mr. J. B. Brown, of Walker, Northumberland, consists in converting the space Northumberland, consists in converged, to between the two arches into an open furnace, to which the ore or mineral is first supplied. ore afterwards descends into the space below the lower arch, which space forms the close furnace.

Mr. Brown levels the top of the lower arch so as
to form an upper bed to receive the ore. This lower arch is strengthened, and the distance between the two arches is made sufficient to allow the ore to be worked on the upper bed or top of the lower arch. The flame passes first over the ore on the upper and open bed, and then under the ordinary lower bed to the chimney. By means of this invention the smelter is able to get rid of any excess of sulphur on the upper bed before adding common salt or other chloride to the ore in the lower bed or close furnace. The gases from the lower bed or close furnace. The gases from the two beds are kept separate and distinct, those from the lower bed being collected and condensed, if necessary. Should it be desired that the ore on the upper and open bed be subjected to a lower degree of heat than when in the lower bed or close furnace, this is effected by causing the flame from the fuel to pass first under the tiles which form the floor of the lower bed, and then ascending to pass over the ore on the floor of the upper bed, and thence to the chimney. It may also be effected by causing the flame from the fuel to pass under the tiles of the lower bed, then between the arch of the lower bed, and a set of tiles made to form the floor of the upper bed, and then finally over the ore on the upper bed to the chimney.

Fig. 1 of the accompanying engravings is a

sectional view of a combined close furnace and open furnace, constructed according to this invention. A is the lower bed or close furnace; B is the lower arch, and C the upper arch; D D are the spaces or flues under the tiles of the lower bed A; E E are the working doors. He levels the top of the lower arch B to form an upper bed F. The of the lower arch B to form an upper bed F. The flame passes first over the ore on the upper bed F, and then under the lower bed A, through the spaces D D, to the chimney. If, as we have before explained, it is desired that the ore on the upper bed F should be subjected to a lower degree heat than that on the lower bed A, the flame is caused to pass first through the spaces D D, and then to ascend and pass over the ore on the upper bed F to the chimney. Fig. 2 represents a modi-

fied arrangement of Mr. Brown's furnace, in which spaces or flues G G are formed between the lower arch B and the upper bed or open furnace F. In this furnace the flame is caused to pass through the spaces D D, then through the spaces G G, and finally over the ore on the upper bed F to the THE TITANIFEROUS IRON-SANDS OF CANADA.

T the Lyceum of Natural History, New York, Professor Eggleston mentioned the Moisic iron as being of excellent quality, being in toughness, purity, and fibrous structure, as fine as any in the world. A railroad axle,  $2\frac{1}{2}$ in. to 3in. in diameter, made from this iron, was bent up cold; a stout bar, 2in. thick, twisted till it looked like a corkscrew and could be twisted no longer; and it had been submitted to other tests, all of them signally de-monstrating the superiority of this iron. The monstrating the superiority of this iron. The greater was his astonishment on learning that it had been manufactured from the titaniferous ironsands, occurring at the mouth of the St. Lawrence, at the Moisic Iron Works, under the superintendence of Mr. Molson. Here are two novelties; for, in the first place, the manufacture of iron from any sands had never before succeeded, as such finely comminuted material would choke up the furnace, or sift through the charge without undergoing reduction; in the second place, these sands had the additional drawback of containing 12 to 20 per cent. of titanic acid. The sands are worked in a bloomery furnace, the tuyere, however, entering not at an angle, as is usually the case, but almost horizontally, thus increasing the zone of reduction. All of the titanic acid present goes, as such, into the slag (which shows a remarkable tendency to crystallize and gelatinize with hydrochloric acid), while the magnetite present is reduced, and furnishes the finest The question whether this process will be pecuniarily successful will soon be decided by experiments now going on.

THE GREAT AMERICAN RAILROAD.

MR. J. L. WILLIAMS, Government director of the Union Pacific Pailers. the Union Pacific Railroad, to the Secretary of the Interior, has just issued his report, in which he states the result of a careful professional survey of the first 900 miles of the western 1,100 miles, the portion to be built by this company of the great | railroad across the American continent. Upon the basis of the cost of building these 900 miles Mr. Williams estimates that to complete the whole 1,110 miles of track the sum of 38,824,821 dollars will be required, which gives 34,977 dollars as the average cost per mile, leaving a good round profit to the contractors, who, by the way, are nearly all large stockholders in the road. The items which go to make up this grand total of expenditure include a line of telegraph the entire distance, preliminary surveys, rolling stock, and interest on the capital invested. The road, so far as laid, is not considered up to the proper standard for efficient work, and hence large sums for con-struction will need to be expended for some time after trains shall have traversed the entire dis-Mr. Williams, however, pronounces the work up to the average of new eastern roads, and urges not only the necessity but the advantages finishing it after it shall have been put into actual use. The subsidy granted the company for completing these 1,110 miles of road will amount in all to 29,504,000 dollars, or an average of 26,580 dollars per mile, for which United States bonds, bearing interest at 6 per cent., are issued. A sufficient amount of these bonds are retained in the hands of the Government to insure the completion of the road according to a high standard of engineering. Mr. Williams concludes his report by saying that, when the road is fully completed, it should be subjected to a higher rule of inspection than heretofore, and it will then "invite the through commerce between the two oceans, meet the great national objects in view, and secure safety, certainty, and despatch in its traffic."

#### THE PALMER SHELL.

YESTERDAY week, a new shell, which claims to be more efficient in its destructive powers than any other of its class, was to have been tried at Shoeburyness. A large party of officers and gentlemen went down to witness the trial, but they were disappointed, for it was found that the experi mental shells (64-pounders) which had been made would not fit either the time or percussion fuses of the service, with which they were to be tried. Three attempts were made to use them, but in vain, as far as the shell or its powers were con-cerned. They all burst with a terrific explosion.

downwards with peculiar force. Another claim put forward for it is that it breaks its fragments into more than double the number of pieces of the segment shell, and can be produced at one-third the cost of either the segment or shrapnel. Such claims to merit are about the highest qualifications to approval which any modern shell could well possess; most important of all would be its downward fire. For the purpose of testing the properties which this destructive missile is said to have, a special target was erected. It is made of wooden screens 20ft high, and forms three sides of a square 40ft wide by 60ft deep. The floor is formed of a stout white canvas screen, laid on the earth like a carpet. 20ft. in front of this inclosure an ordinary light wooden target is slung by ropes between stout poles. The percussion shell is intended to burst on passing through this first slung target, so that the screens beyond and the canvas below may at once show the effect of its lateral and downward fire. The shell has been tried on board the "Excellent" gunnery ship, and a favourable report given of its powers, and most especially of the force of its downward fire. experiments at Shoeburyness will be resumed when proper fuses are made.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 ls. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. E. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith, Ed. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

#### Meetings for the Aeek.

Mon.-Royal Institution.-General Monthly Meeting, at

Mon.—Royal Institution.—General Monthly Meeting, at 2 p.m.
Society of Engineers.—Mr. Perry F. Nursey on "Explosive Compounds for Engineering Purposes," at 7.30 p.m.
Royal Institute of British Architects.—A Special General Meeting of Members only, to Consider a Report of the Committee on the Metropolitan Buildings and Management Bill, adopted by the Council, June 22, 1868; at 8 p.m.
Liverpool Polytechnic Society.—The First Meeting of the Thirty-second Session will take place at the Royal Institution, at 6.30 p.m.
The Annual Report of the Council will be read, and the Council for the ensuing year elected; after which the adjourned discussion on the President's Address will be continued.
Royal United Service Institution.—Lieut.-General W. N. Hutchinson, on "Recoil Utilized"; and Lieut. C. P. Stone, 77th Regiment, will Exhibi Models Illustrative of his New Gun Platformt at 8.30 p.m.
TUES.—Royal Institution.—Professor Westmacott, on "Fine Art," at 3 p.m.
The Institution of Civil Engineers.—Mr. James Robert Mosse, M. Inst. C. E., on "The Mauritius Railways, Midland Line," at 8 p.m.
THURS.—Royal Institution.—Professor Odling on "Hydrogen and its Analogues," at 3 p.m.
SAT.—Royal Institution.—Professor Odling on "Hydrogen and its Analogues," at 3 p.m.
London Association of Foremen Engineers.—Ordinary Monthly Meeting. Mr. Laird on "The Epicycloidal Engine, an Effort at Improved Screw Propulsion," at 8 p.m.

THE MANUFACTURE OF WATCHES AND CLOCKS.—A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices, and no one should make a purchase with their prices, and no one should make a purchase without visiting the above establishments or consultvain, as far as the shell or its powers were concerned. They all burst with a terrific explosion, that sent their pieces roaring and hissing through the air in all directions, but owing to their fuses fitting badly they all burst after passing through the targets and over the sea. The shell is the invention of Mr. F. Palmer, and its chief merit consists in its scattering its deadly fragments, not only in a horizontal and lateral direction, but also

### Nabal, Military, and Gunnery Items.

The total cost of the Prussian war of 1866, as verified by the Berlin Court of Accounts, amounts to £22,624,600, and of which £109,364 was for secret political purposes.

MESSRS. A. STEPHEN AND SONS, of Kelvinhaugh, have contracted to build for Messrs Handyside and Henderson a first-class screw of 2,200 tons, as an addition to the "Anchor line" of Transatlantic steamers.

WE learn that the Porte has purchased the two ironclad corvettes built for the Chilian Government—but rejected for alleged non-compliance with the contract—at Bordeaux. The Greek Government was also negociating for these vessels, but has, presumably, been outbid. The Porte has bought them at the high figure of £180,000.

An impression appears to prevail that, among the new schemes of the Government, will be one to favour a shorter term of enlistment, by keeping a certain number of infantry battalions always at home, and a certain number in effect localized—in short, never relieved—in India. This would have a very beneficial effect in easing the reliefs, and there does not appear to be any serious practical difficulty in carrying out such a plan.

The latest Washington despatches state that Vice-Admiral David D. Porter will be appointed Secretary of the United States Navy, pro tem., and will hold the office until the naval survey, which creates three admirals, is completed and approved. He will thereupon resign and accept one of the three offices so constituted. General Schofield will take position in the Cabinet on the same conditions, and thus the recent projected legislation in the Senate about limiting the number of offices to be held by one person will be avoided in these two particular instances.

IT has been intimated that it is not the intention of It has been intimated that it is not the intention of the Government to fill up the varancy in the Government to fill up the varancy in the Government of Greenwich Hospital for so long a period held by the late Sir James Alexander Gordon, who was in receipt of £3,000 a year from the Hospital funds. On Tuesday last, Mr. Trevelyan, of the Admiralty, accompanied by his secretary, paid a lengthened visit to the Hospital, inspecting minutely the whole building, with a view, it is said, to its being occupied for military purposes, it being the intention, in October next, to remove the infirm pensioners to the hospital at Netley.

Wa ("United Sewrice Grants") we have a labeled to the content of the service of the content of the labeled to the labeled to

WE ("United Service Gazette") understand that WE ("United Service Gazette") understand that important changes have already commenced in the Coastguard Department. The separate establishment in Spring-gardens is, we believe, to be broken up; and the offices of Controller General and Deputy Controller General are to be abolished. Some of the more efficient heads of departments will be transferred to the Admiralty in Whitehall, and a number of the junior clerks either pensioned off or dismissed with a gratuity proportioned to length of service. The intention is, we understand, to amalgamate the various branches of the moribund establishment with the corresponding branches in the Admiralty. the Admiralty.

A GUN carriage and slide of a novel and very ingenious construction, by Messrs. Vavasseur, of the London Ordnance Works, for a 7-inch steel built-up rifled gun, was tested on Saturday, at Yarmouth, with the highest success. The compressor, which is the most important feature, consists of a cone and drum, working under a brakestrap, this friction gear being attached to the lead of a long screw-shaft, actuated by a nut under the carriage, moving along it and turning it round. The great value of the system is that the compressor is always ready to be acted upon by the recoil, and is automatically put into gear the moment the gun is automatically put into gear the moment the gun carriage begins to move.

THE Sydney correspondent of the "Times" writes The Sydney correspondent of the "Times" writes:

The Rifle Association has just finished its matches, and I think when the Wimbledon authorities come to see the results, they will say, there is no better shooting in the world than we show in our "All compering the performances at Wimbledon with the performances at Sydney with the performances at Sydney at the comers' match." On comparing the performances at Wimbledon with the performances at Sydney at the 1,000 yards range, I see that the first man in each was only three below the highest possible score, and that the lowest score made by the first ten men at Sydney was only six marks below the standard, where at Wimbledon the lowest score made under the same circumstances was fifteen marks below the highest possible. This certainly looks like an advantage. The Enfield shooting was not quite so good as last year, but the small-bore was superb.

Armstrong branch has been shut up for a considerable time with all its expensive machinery considerable time with all its expensive machinery, in consequence of a large order being given for the conversion of guns from the smooth bore into rifled guns upon the Palliser principle, to be effected at the Elswick Factory, instead of at the Government establishment at Woolwich.

ARRANGEMENTS are being made for the construction of iron gun carriages for the navy at the Chatham Dockyard, though recently certain buildings in the Royal Carriage Department, Royal Arsenal, had been altered and fitted up with plant and machinery to carry on the works at agreat cost. The removal of the naval carriages to Chatham will lead to part of the Carriage Department being closed. In the Royal Gun Factory Department, the

UNDER the title of a Permanent Exhibition og Inventions and Improvements, a new section habeen added to the Museum of Agriculture in Bussis been added to the Museum of Agriculture in Russia The object of this new section is to supply those who have invented or improved agricultural machines, implements or methods, with ready means of communication with agriculturists and the public. The machines, models, plans, or drawings are to be exhibited gratis for six months, at the expiration of which time they will be returned to the inventors or destroyed, unless they should have been purchased for the Museum.

On Friday last a most destructive accident occurred On Friday last a most destructive accident occurred at the establishment of Messrs. Martin and Johnson, manufacturers. The mill locomotive engine ran away, making the whole engine-house a wreck of machinery. Two engines of 50-horse power each were smashed into fragments. The flywheel, weighing 30 tons, was broken up, and the fragments thrown about, doing injury in all directions. No lives were lost. Seven hundred people are thrown out of work, and it will occupy six months to repair the damage. The loss in machinery and property is stated at £6,000. the damage. The stated at £6,000.

A curious discovery has been made in the Cathedral Close of Lichfield. In clearing the ground for the foundation of some additional building to the bishop's palace, the ashlar facing of the old palace was laid bare at a few feet below the present garden level. Built up against this wall were found the remains of a pipe manufactory. The flue and the floor of the kiln were very apparent, formed of bricks of a larger size than the present common Flamish pattern. Mixed with the surrounding soil were pipes and fragments of pipes to the amount of one or patients. Mixed with the surrounding soil were pipes and fragments of pipes to the amount of one or two hundred, portions of the unbacked clay still quite moist, scorise and lumps of coal, and in one case, a fully-formed pipe bowl in its unburnt state,

case, a fully-formed pipe bowl in its unburnt state,

THE Australasian gold fields appear to have decidedly increased in productiveness last year. The returns for the year are not finally made up, but it appears that the total value of the imports effected to November 30, was £6,356,192, as compared with £5,291,014 in the corresponding period of 1867, and £6,281,613 in the corresponding period of 1866. In 1867 (whole year) the value of the Australasian gold imported was £5,801,726; in 1866, £6,840,718; in 1865, £5,001,491; in 1864, £2,657,133; in 1868, £5,001,491; in 1869, £8,571,867; in 1869, £8,677,864; and in 1858, £9,066,289. New South Wales, Queensland, and New Zealand all appear to have made increased deliveries of gold last year. deliveries of gold last year.

THE Imperial Society of Natural Sciences of Moscow, whose object is the fitting out of scientific expeditions, the establishment of museums of natural history, and the organization of exhibitions, has just held its fifth annual meeting, and seems to have been activaly employed. As expedition into Turkistan has just been arranged with the assistance of General Kaufmann and M. Henis, and three other avneditions have recently hear fitted out at the or General Kaulmann and M. Henis, and three other expeditions have recently been fitted out at the expense of the Society—one along the banks of the Black Sea, a second to the Lakes of the district of Rissas, and a third to the Lake Fresta in the Moscow district. It proposes, with the aid of M. Daschkoff, an honorary member, to establish an aquarium at a cost of 30,000 roubles.

ost of 30,000 roubles.

PROBABLY, Swanses, situate in the midst of copper smoke, patent fuel smoke, iron works smoke, and smoke from chemical works of almost every description, is one of the healthiest, if not the healthiest, in the United Kingdom, size and population being considered. The report of the medical officer of health of the borough (Mr. Ebenezer Davies) for the past quarter, has just been published, which shows some remarkable figures. Taken over the three months of the past quarter, the annual death rate was only 15-8 per 1,000 of the population, while the death rate for the past month of Desember actually was as low as 12-5 per 1,000. Seventeen persons died above 70 years of age, of whom five were above 80 years, and one woman died at the age of 101 years. The late admirably-constructed system of sewerage and the abundant supply of water, both carried out by the local board of health, have doubtless contributed to this satisfactory state of things.

A CORRESPONDENT from Syracese, New York,

buted to this satisfactory state of things.

A CORRESPONDENT from Syraces, New York, sends to the "Scientific American" an account of an invention perfected in that city for mixing mortar, which is simply this:—The lime is first slaked in a vat with water enough to make it to a paste, and sllowed to retain its heat for about twenty-four hours. It is next run off into a second vat, from which it is pumped by a chain pump to a revolving cylinder that has a large quantity of spikes on the inside. As it flows from the cylinder, it passes through a sieve of tan meshas to the inch, and every particle that is used has to go through these very fine holes no larger than a pin's head. From this machine it falls into a large vat, from which it is pumped as required to a similar revolving machine called the mixing machine, into which it flows in a continuous stream, and sand, previously sifted, is added at the rate of about eighty bushels per hour. The mortar made in this way is said to be of a very superior quality.

### Patents for Inbentions.

#### ABRIDGED SPECIFICATIONS OF **PATENTS**

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILBRS AND FURNACES-2181, 2198, 2226, 2239 BUILDINGS AND BUILDING MATERIALS-2188, 2237

CHEMISTRY AND PHOTOGRAPHY-None.

CULTIVATION OF THE SOIL, including agricultural imple ments and machines-2176, 2233, 2243

ELECTRICAL APPARATUS-None.

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.-2173, 2183, 2194, 2203, 2214, 2219, 2238, 2242

FOOD AND BEVERAGES, including the apparatus for pre paring food for men and animals-None

FURNITURE AND APPAREL, including household utensils. time-keepers, jewellerv-musical instruments, &c.-2180, 2197, 2199, 2205, 2228

GENERAL MACHINERY-2174, 2190, 2195, 2200, 2204, 2208 2216, 2217, 2234, 2235

LIGHTING, HEATING, AND VENTILATING-None.

METALS, including apparatus for their manufacture-2177, 2206, 2207

MISCELLANEOUS-2171, 2172, 2175, 2178, 2179, 2184, 2189, 2193, 2196, 2201, 2202, 2209, 2211, 2215, 2220, 2223, 2224 2225, 2227, 2229, 2230, 2231, 2232, 2236

2171 E. ROUGET, Paris. Fixing drawings on paper. Dated July 9, 1868.

This invention consists in obtaining the fixation of such

Dated July 9, 1868.

This invention consists in obtaining the fixation of such drawings, tracings, or sketches by directly projecting on these latter any suitable adhesive liquid reduced to fine sprsy, or in what is commonly called the atomized or pulverized state, by causing the liquid to pass rapidly under pressure through one or more capillary tubes or openings. By this method the defects of the trunsudation process are entirely done away with, besides which the operation is executed in a less time, and may be performed at once by the artist without the slightest difficulty. As for the fixation liquid, any colourless or nearly colourless liquid, which allows of being atomized, and which, after the coming dry, causes the particles of the charcoal or other drawing materials made use of to adhere sufficiently firmly to the paper or other drawing surface, may serve for the purpose. Thus, for instance, a liquid which has given the patentee the most satisfactory results is obtained by adding to a solution of 302. of white sugar candy and 202. of white shellac, in about two pints of spirit of wine, a decection of about 102. of facus crispus in one pint of distilled water.—Patent completed.

2172 M. BEBRO, Manchester. Ticket deliverer. Dated July 9, 1868.

2172 M. Bebro, Manchester. Ticket deliverer. Dated July 9, 1848.

This relates to two descriptions of apparatus, one intended for portable purposes, and the other fixed or stationary, and may be used on a desk, ledge, or counter. The first part consists in so applying one or more indiarabber surfaced bowls or delivery rollers, and in using them in combination with the interior surface of the lid of the box containing the strips or roll of consecutively numbered tickets, that when the lid is securely closed it presses on the bowls, and when the strip of ticket is between it and the shaft the roller is turned by a handle, the issue of the tickets is thereby effected from an aperture or slot in front of the rollers; a guide is also arranged to ensure the even issue, and a stop plunger to hold the ticket when being form off. In order to ensure the even delivery of the strip, and to prevent it becoming twisted or crumpled, each roller is subdivided into discs, and the divisions so formed in the rollers are filled with a flat plate made to fit between the discs and to extend up to the mouth of the aperture, and the rollersare also enclosed below and within a curved shield, which combined form a guide for the strips; and in order to hold the strip when a tacket is being form off, plungers are so arranged that when pressed outside by the hand they set on the strip and hold it. The size and shape of the box, and number of delivering shafts and rolls of tickets, may vary with requirements. The second part, relating to the fixed or stationary apparatus, consists in transmitting an intermittent movement to the said delivering rollers (the ticket guide being constructed as previously described) by the use of spur and ratchet gearing actuated by a lever or handle, which, when acted upon, expels a ticket from the sperture in the box with each downward movement of

the handle. At the delivery end another roller is arranged by which the strip of tickets may be set or adjusted to the lines of perforations so as to present exactly one ticket beyond the opening, and so prevent the ticket following being damaged.—Patent completed.

2173 W. HADFIELD, Ardwick, Looms, Dated July 9.

2173 W. HADFIELD, Ardwick. Looms. Dated July 9, 1868.

This relates to the two parts of the loom known as the "letting off" or beam motion and the "taking up" or cloth roller motion, and the invention is designed for the purpose of producing, through their combined action and the great precision with which the motion can be regulated, a more perfect, uniform, and even fabric than has hitherto been manufactured. The warp or thread, on leaving the beam, passes around and between two rollers geared together, and between the surfaces of which the warp in its passage is nipped by reason of the top roller being mounted in slide bearings that causes its periphery at their nipping surface or points of contact to be somewhat below the top surface of the under roller, the top roller relative to the bottom being very slightly increased in diameter. The warp, as it leaves the nipping surfaces of the rollers, its delivered and transmitted to the taken up at a more uniform and even tension than hitherto, the tension being up whilst shedding by allowing it to pass after leaving the top roller over an ordinary vibrator. The taking up of the cloth when leaving the breastbeam is effected in a similar manner to the letting off, that is, the cloth is retained or nipped between the periphery or surface of two rollers geared together, their arrangement and position being similar to the rollers stready described, the under roller, in place of the top, being still further increased in diameter, or as an equivalent one of the wheels gearing the rollers may be varied or a little larger in diameter. The cloth is received and delivered from the lower roller on to the cloth roller, where it accumulates in the ordinary manner. Rough material, such as emery or perforated zinc, now in general use for the taking up, is entirely dispensed with. The connection of the letting-off with the taking-up roller is accomplished in the ordinary manner, through the medium of the ratchet wheel, which is provided with a long boss, on which the spur wheel or

2174 J. CHANDLER, Mile End-road. Preventing waste of

2174 J. CHANDLER, Mile End-road. Preventing waste of water. Dated July 9, 1868.
This consists of one cistern divided into two parts, one discharge or outlet valve, one communicating valve, and one ordinary ball valve. In this apparatus the discharge division of the cistern must be capable of containing the maxisuum quantity of water. The opposite division of the cistern contains the ball valve. The ball valve is, from its peculiar position, entirely dependent upon its own self-action in either opening or shutting.—Patent abandoned.

peculiar position, entirely dependent upon its own self-action in either opening or shutting.—Patent abandoned.

2175 E. J. MAYALL, Bridge-row. India-rubber type. Dated July 9, 1868.

In carrying out these improvements, in the case of india-rubber, the patentee combines with, say, 8lb. of that material, 5lb. of sulphur that has been washed or prepared to remove as much as possible of the acid from it, and about 2lb. of whiting, or black or white lead previously dried. The compound thus obtained is then well mixed or ground together by the aid of heated rollers, or other suitable means. When a thorough mixture has been obtained, the matters are placed in a mould or moulds of the desired form, and apply pressure thereto, so that the rubber may fully occupy the parts of such mould to the thickness desired. The mould is then subjected with the contained india-rubber, which has been acted upon by heat, to harden such rubber. Suposing the blocks obtained to be about 10 in. in thickness, then the heat for the first two hours may be about 233deg, then the next two hours about 250deg, the next two hours about 296deg. In treating gutta-percha, the patentee combines with, say, 8lb. of that material 4lb. of sulphur, washed or prepared to remove acid therefrom, and 2lb. of whiting or plack lead, either of which has been previously dried. These matters are then caused to combine together by grinding between heated cylinders, or otherwise. And then, for the hardening process, the gutta-percha so treated is placed in moulds pressed and subjected to heat, which for a thickness of lin. of the material may be for the first hour, 230deg. Seventh hour, 260deg.: fifth hour, 270deg.; sixth hour, 250deg.; seventh hour, 260deg. In treating a combination of india-rubber and gutta-percha, the patentee, to 4lb. of gutta-percha, from which all has previously been removed, 4lb. of india-rubber and gutta-percha,

2176 W. CREASY, Bedfield, Suffolk. Drying grain. Dated July 9, 1868.

This invention consists in the employment of a revolving cylinder through the centre of which, and lying in the same direction, is a fixed hollow tube, supported at the ends by standards or the general framework of the machine; upon this hollow tube the cylinder is arranged to revolve by the application of friction rolls, or by other suitable means. The cylinder is arranged to revolve in a lateral or horizontal position, and when used for operating upon damp grain the patentee prefers clothing it with perforated or woven iron or zine placed around its circumierence. The filling is effected by means of a hopper, from

which there is a passage into the interior of the cylinder, running in a diagonal direction through the stationary tube, and communicating with the hopper to the outside of the cylinder at the upper end with the interior of the cylinder at the lower. The progression of the grain through the cylinder is effected by being carried by the action of the revolving cylinder against some blades, which are fixed at an angle to the stationary tube; it is then discharged at the further end in a similar manner. Sliding valves are conveniently arranged for regulating the progression of the grain or other substances through the cylinder, either at the feed or the discharge end, or both. The quantity of grain or other substance is regulated in the cylinder by the feed pipe, the delivery end of which is brought higher or lower in the cylinder; for instance, if the cylinder is to be kept constantly one-third full, then the delivery pipe would project to the lower part of the cylinder, and if necessary to keep it half full, the delivery would be higher. Some kinds of grain that are washed and dried, such as Exyptian wheats, are treated in the following manner:—A small perforated pipe is employed, which runs through the cylinder by the side of the stationary tube, and is flixed to the eccentric pieces; water is fed into this pipe through an opening in the eccentric piece; when the cylinder is revolving, the effect of this, by the motion of the corn against the blades, and the water descending upon it, is to wash and break up the dirt, which falls with the water through the perforated exterior of cylinder; after being sufficiently washed, the heated air is turned on, and it is dried before leaving the cylinder.—Patent completed.

leaving the cylinder.—Patent completed.

2177 J. HARRIS and V. PENDRED, Dulwich. Iron and steel. Dated July 9, 1868.

In carrying out this invention, a furnace is constructed of the reverberatory type, in which is placed a grate at one end, separated by a brick bridge from a forging hearth or chamber. This chamber or forging hearth is fitted with three openings, one at the end opposite the grate; the remaining two are disposed one at each side and opposite each other. The openings are fitted with suitable doors, by which they may be closed at pleasure. At one side of this furnace is erected a horizontal steam hammer, and at the other a hydraulic anvil. The hammer is so disposed that its head or tup may enter one of the lateral openings, while the hydraulic anvil may be introduced through the other to a distance which may be regulated at pleasure. Any requisite quantity of cast iron is melted in one or more pudding furnaces, and puddled in the ordinary way; as soon as the iron has come to nature, it is converted into balls or blooms in a way well understood and commonly practised. The puddler then takes one of these balls and places it in the forging hearth before mentioned, which is maintained at a high temperature by the heated air and products of combustion proceeding from a fire previously made on the grate. The anvil is then introduced, and the steam hammer is caused to strike and flatten the ball thus introduced. The puddler then brings another ball, which is placed close to the first, and welded to it, and other balls are introduced, and welded to the flort wo, until a mass of the required size is produced, when the anvil is withdrawn, and the mass is pushed out of the forging hearth, through the opening provided for the introduction of the anvil, on to a suitable truck or other contrivance, and is then taken away to be rolled, hammered, or otherwise dealt with.—Patent completed.

2178 J. MABSON, Norwood. Swimming apparatus. Dated

2178 J. MABSON, Norwood. Swimming apparatus. Dated July 9, 1868.

This apparatus consists mainly of a flexible blade or surface, shaped like the tail of a flexible blade is carried on the end of a longitudinal beam, bar, or tube, the opposite end of which is connected to a belt to be passed round the waist or body. A crossbeam, bar, or tube is jointed to the longitudinal beam, and the ends of this crossbeam carry suitable appliances for securing the feet beam carry suitable appliances for securing the feet thereto; rods lead from the ends of the crossbeam to the outer end of the longitudinal beam near the blade.— Patent abandoned.

Patent abandoned.

2179 H. H. DOTY, Bury-street. Signalling lamps. Dated July 9, 1863.

This consists of a hollow vessel for obtaining petroleum or other hydrocarbon oil, supported on a stand, and having an aperture through its centre for the admission of air to the flame. A tube having a nozzle at its upper end passes up through the aperture, and is in connection with an air pump, by which means a current of air is forced through the nozzle at the end of the air tube. Close to the critico of the nozzle, and at right angles thereto, is another nozzle lixed on a pipe in communication with the petroleum or other hydrocarbon oil. The draught caused by the current of air creates a vacuum in this pipe, thereby drawing the petroleum or other hydrocarbon oil up the pipe and ejecting it from the nozzle and the form of spray, which is ignited by the flame of an oil lamp placed in or on the oil vessel, the flame burning close to an aperture opposite the nozzle through which the spray is ejected. The petroleum or other hydrocarbon oil is fed to the oil vessel through an opening closed by a screwed cup or other contrivance. A covering of wire gauze or other suitable material is placed over the flame to provent its being extinguished by wind or draught, and beneath the oil vessel is a pan for catching particles of spray that have not been ignited, the said pan being emptied when required by a cock affixed thereto. Resting on a bracket placed around the oil vessel, or on the oil vessel itself, is a hexagon or other shaped glass lantern, having strengthening ribs up its sides and supplied with a metal or other covering, having an opening at the top for the escape of the heat. A reflector of any suitable material is placed over three sides of the hexagon or about one-half of the glass lantern, so that on turning it slowly more prolonged flashes result, or the flashes may be caused by turning as cook in the hose connecting the "light" with the air pump. Also in grooves formed by the strengthening ribs various coloured pieces of

2180 T. NUTTALL, Bury, Lancaster. Harnes. (A communication). Dated July 9, 1863.

The patentee covers the portion of the body of the collar that is brought in contact with the horse with a fabric whose exterior surface has been rendered waterproof by a

coating composed of vulcanized caoutchout or guttacoating composed of valcanized cacutchout or gutta-percha, or any other composition possessing a sufficient portion of the said gums to produce an elastic and durable waterproof coating on woven fabrics. Similar waterproof fabrics are also employed for the bearing surfaces of riding and harness saddles, and any harness bearing on the horse.—Patent abandoned.

2181 W. R. ASTWALD, Sunderland. Tube joints. Dated

2181 W. A. July 9, 1868.

This consists in making ferrules or short tubes of compressed paper for the ends of the tubes of, say, surface condensers, and fixing the paper so as to form a tight joint between the plate and the condenser tube.—Patent com-

2182 T. WORTH, Rochdale. Railways. Dated July 9

2133 I. WORTH, ROCHORIE. Ratings. Dated July B. 1868.

This invention consists, firstly, in a method of dispensing with turntables, for which purpose the patentee proposes to lay rails in a curve leading from one line to another; when, therefore, the engine is run round the curve, it becomes reversed upon the other line without the use of a turntable. Second, in a method of dispensing with chairs. For this purpose longitudinal metallic sleepers are employed, and the rail is riveted or bolted thereon. The longitudinal sleepers are formed with or without vertical flanges bolted together to form a continuous length, and crossbars are adapted from right to left hand rail, by which means the rails are kept at correct distances apart. Or instead of bolting or riveting the rails to the longitudinal sleepers they are formed in one piece.—Patent completed.

rail, by which means the rails are kept at correct distances apart. Or instead of bolting or riveting the rails to the longitudinal sleepers they are formed in one pieco.—Patent completed.

2183 A. M. CLARK. Chancery-lane. Looms. (A communication). Dated July 9, 1868.

The improvements consist, first, in an improved combined arrangement of temple or stretcher and take up; second, in an improved arrangement of warp thread bobbin. It is well known that in weaving corsets, gaiters, and such like articles of irregular form, the weft is first passed across the entire width of the warp foundation, and in making the neck or hip of the stay, for example, the threads are woven to the right or left of the warp, that is to say, the weft, as the weaving proceeds, is passed through a gradually decreasing number of warp threads, so as to form a gusset. The weft is then again passed through the whole breadth of the warp, a second gusset made, and so on, until a sufficient number are formed to obtain the necessary fulness at the neck or hip of the stay. When the weft passes through all the warp threads, the rollers revolve at equal speeds and take up the full width of fabric; and when, on the contrary, the weft only passes on one side of the fabric, through a certain number of warp threads, the cards of the jacquard are pierced, so that those rollers only turn which are opposite that portion of the fabric. The connection of this system of regulators, working independently of each other, to form the gussets, it may happen, by reason of a disarrangement of the jacquard mechanism, that some of the hooks will not catch or pierce the card, producing a draft. In this case, an opening would be left in the fabric, and supposing the hook were not raised, a ridge would be formed by the fabric being drawn together. Further, in order to facilitate the operation, supposing the width of the jacquard requires forty cords for raising the lovers of the rigulators, it is difficult to pass the hand through to connect any of the warp threads whic

Patent completed.

2184 J. H. JOHNSON, Lincoln's Inn. Murical instruments. (A communication). Dated July 9, 1888.

The invention relates principally to that class of wind musical instruments known as accordions, and to other musical instruments provided with free reeds or tongues, and consists in the adaptation of the planoforte system of keyboard without impairing the impressiveness of the instrument, and in the application of other improvements, whereby a more regular action of the bellows, and a greater compactness of the parts, are obtained, and the harshness of tone to which the ordinary instruments of small size are liable, is considerably diminished. The patentee employs a double pair of bellows on the system used in ordinary organs which work with a crank or handle, but in lieu of using a bellows composed of one movable part, two movable parts are employed for each pair of bellows, such parts being connected together by wire at their moving extremity, and space being left between them to admit air through the valves with which they are provided. These movable parts are hinged at their other ends to the top and bottom sides of the bellows, instead of a fixed plece attached thereto, as in the ordinary manner.—Patent completed.

2185 W. L. G. WRIGHT, Lanark. Rotary engines and

2185 W. L. G. WRIGHT, Lenark. Rotary engines and pump. Dated July 10, 1868.

The specification of this patent is very voluminous. The patentee claims two concentric annular cylinders having open ends, the covers being fixed to the framing. Second, the pistons which are hinged and made to slide back into recesses. Third, the mode of packing the gravitating pistons, and the switch stuffing box; and, fourth, the placing of a condenser in the casing, all as described.—Patent completed.

2186 E. T. HUGHES, Chancery-lane. Wood parement.
(A communication). Dated July 10, 1868.
The patentee employs two sets of blocks or a set of

blocks and strips. One set of blocks forms, when the pavement is completed, the wooden surface of the pavement, and the other or auxiliary set of blocks, and forms no part of the wooden surface of the pavement, but determines the size of the groove or channel way between the principal blocks, which is afterwards to be filled with broken stone, gravel, and tar.—Patent completed.

2187 C. E. BROOMAN, Fleet-street. Cutting and utilizing drailway rails. (A communication). Dated July 10,

1868.
The rails are cut longitudinally about the middle of the web connecting the head and the bottom or the two heads in the case of double headed rails. This is effected by guillotine shears, in the manner described.—Patent abandoned.

2188 G. DAVIES. Lincoln's Inn. Filling spaces between floorings. (A communication). Dated July 10, 1868. This consists of hollow filling pieces of peculiar form, made of brick earth pressed into moulds and dried in the air; without burning. These are placed between the iron beams or joists of the flooring or ceiling.—Patent abandoned. abandoned.

abandoned.

2189 J. JEFFREYS, Tottenham Court-road. Stude and buttons. Dated July 10, 1868.

The head of the stud or button is made of a crescent shape, by stamping out or otherwise removing a portion of the disc. The horns or points of the crescent are more readily introduced into the button hole than the disc, it being simply necessary to insert either end of the crescent. being simply necessary to insert either end of the crescent-shaped head and then partially rotat he stud, in order to attach it to the article.—Patent completed.

shaped head and then partially rotat so he stud, in order to attach it to the article.—Patent completed.

2190 J. D. CHURCHILL, Oxford-street. Hot-air engines.
Dated July 10, 1868.

This relates more particularly to the formation of the bedplate in which the air passage is cast on or attached to its under side. This passage turns upwards and communicates with a vertical air passage cast on or attached to the receiver or main casting which contains the fire-box.—Patent completed.

2191 F. R. A. GLOVER, Isle of Wight. Fishing ships' anchors. Dated July 10, 1868.

The patentee adapts to one of the arms of the anchor a many ship is capable of sliding or varying its position along the arm of the anchor from the crown to the palm. This ring may, if desired, be hinged or jointed, so that it may be removed from the anchor, if required, and to it is attached a light chain of sufficient strength to lift the anchor. The other end of this chain is attached to any convenient part of the cable, so that, if desired, it may be drawn therewith through the hawse hole, in order that it may be laid hold of for the purpose of lifting by its palm the anchor to the cathead, and thereby fixing the anchor.—Patent abandoned.

2192 G. DAVIES, Lincoln's Inn. Armour. (A communication)

—Patent abandoned,
2199 G. Davies, Lincoln's Inn. Armour. (A communication). Dated July 11, 1868.

On a basis of rough network or cellular structure is secured another series of bands slightly narrower than the preceding, and by adding alternate ranges of longitudinal and vertical bands of decreasing widths until the required thickness is attained, the result being the formation of a series of rough pyramids, more or less square, and more or less perfect. To this network is bolted or otherwise secured a plate of malleable iron for the double purpose of producing an even surface, and of hermetically closing the pyramidal cells, so as to prevent the deposit or accumulation therein of water.—Patent abandoned.

2193 W. Russell. Lamb's nassace. London. Paper bag.

closing the pyrainidal cells, so as to prevent the deposit or accumulation therein of water.—Patent abandoned.

2193 W. Bursell, Lamb's-passage, London. Paper bag machinery. Dated July 11, 1868.

To the end of the bag or envelope machine a frame is attached, over which the continuous sheet of paper passes in its passage to the machine to form the bags. This frame carries a transverse shaft working in bearings, at either side of frame to which shaft are keyed two cutters or stamps, one at either side of the strip of paper, at such a distance apart as to cut off a narrow strip from both edges of the paper each time the cutters are brought down thereon.—Patent completed.

2194 T. Travis. W. H. Prince, and J. Tominson, Rochdale. Finithing yarn, &c. Dated July 11, 1868.

This consists in applying a gas burner or other equivalent to act on the yarn or thread as it passes from one of the spools or bobbins around which it is wound to the other, or before or after it has passed round the caps, spools, or bobbins, or other friction apparatus.—Patent completed.

2195 J. S. Nibes, Birmingham. Pumps. Dated July 11

2195 J. S. Nibbs, Birmingham. Pumps. Dated July 11

1868.

A single piston rod is employed, which is provided with two valves, one valve being attached near the centre of the piston, and the second at or near its lower end; a third valve is secured at or near the bottom of the cylinder and below the lowest valve of the piston; the piston rod is worked up and down in the cylinder by means of a handle, and the cylinder is furnished with a base or foot rest for steadying the action of the pump.—Patent abandoned.

doned.

2196 T. King, Spitalfields. \*\* Bungs. Dated July 11, 1868.
A ring is screwed into the ordinary bung hole of the cask until the fiange rests upon the surrounding surface; screws or rivets may be inserted into these holes, and the cask stave for greater security. Beyond the diameter of the internal screw a recess is formed in the fiange end, with a half circular groove in the face of it. The inner ring, which is sometimes made solid, is formed with a thread or screw on its external surface, and a fiange at one end, of a diameter slightly less than that of the recess formed in the fiange of the outer ring; likewise a corresponding half circular groove cut in the under side of the fiange, and into this groove a ring of india-rubber or other suitable substance is inserted.—Patent abandoned.

2187 B. MACKIE Stewarton. N.B. Cane. Dated July 11.

2197 R. MACKIE, Stewarton, N.B. Caps. Dated July 11,

This consists in stiffening the crowns of "Scotch caps" by the employment of an agent, such as shellac, in order to make it more handy to lift on and off the head.—Patent completed.

completed.

2198 J. D. BRUNTON, Kentish Town. Tools for cutting rock. Dated July 11, 1868.

This consists of a chisel, the cutting edge of which is curvilinear, or of the nature of a gouge, bevelled towards the hollow or concave side, and straight down the back or convex side, the object of which is to cause the chisel to cut grooves or slots in the rock, either in sits or when detached from its bed. The machine to which the tool is attached consists of a bed, with slides resembling a lathe bed, so constructed that the chisel, when in operation,

may be moved the whole length of the intended groove to be cut, and as close as possible to one side of the bed.— Patent completed.

Patent completed.

2199 C. E. BROOMAN, Fleet-street. Locks. (A communication). Dated July 11, 1863.

This consists in providing locks, chiefly for post-office purposes, with wheels or indicators, each marked with the figures 0 and 1 to 9 inclusive, which wheels or indicators are connected with certain mechanism inside the lock, so that the lock cannot be opened without a change being made in the numbers on the indicators, as seen through small apertures in the face of the lock. The numerals on the said indicators are capable of 999 changes more or cless, which changes cannot be repeated without the destruction of a seal made of lead or other material.—Patent completed.

Patent completed.

2200 H. GARSIDE, Manchester. Cutting files. Dated July 11, 1868.

The cutting tool is held at the lower extremity of a ram which slides freely in guides attached to or forming part of the framing, and to which ram a reciprocating motion is given by the combined action of a cam on the driving shaft, which lifts the ram, and a spring which re-acts and gives the necessary blow. The feed motion for spacing the teeth consists of a guide screw working in bearings at the ends of the bed, actuated by a ratchet wheel and pawl, and engaging with a clasp nut attached to the slide.—Patent abandoned.

2201 E. EDWARDS, Baker-street. Photography. Dated

2201 E. EDWARDS, Baker-street. Photography. Dated July 13, 1868.

This consists in rendering gelatine, &c., insoluble by the use of ammonia-alum, iron-alum, and other substances containing similar properties, so that photographs may be taken and fixed on the gelatine so prepared.—Patent completed.

pleted.

2202 J. N. WILLIS and S. Judd, Gravesend. Comb syringe. Dated July 12, 1868.

The syringe of india-rubber, or some other elastic material, is connected by a screwpiece and a comb which has a hollow back; small holes are pierced through the teeth or between same, as occasion may require, into the hollow back. The syringe when filled with oil, dye, hair wish, or whatever material desired to be used, is connected with the comb by means of the screw, and together form one article.—Patent completed.

2202 W. J. Hanger Clerk heaten. During. Dated Intel 18.

2203 W. J. HANSON, Cleckheaton. Dyeing. Dated July 13

This consists in enclosing or covering the hanks or slivers with netting or netted fabric, canvas, or other open fabric, to prevent them being rubbed during the process of dyoing.—Patent abandoned.

2204 G. B. PURICELLI, Bedford-square. Printing. Dated

dycing.—Patent abandoned.

2204 G. B. PURICELLI, Bedford-square. Printing. Dated July 13, 1863.

The apparatus in this invention consists of a spring cylinder fitted to rotate on a fixed axis, carried on a frame provided with a handle. Around the circumference of this spring cylinder is placed a strip of india-rubber or other material, on which are formed the letters or design to be marked or printed. An adjustable inking roller is mounted in bearings on the frame in front of the printing cylinder against which it is caused to bear by the aid of springs attached to the movable axis of the printing roller. On either end of the printing cylinder is raised an india-rubber band or rim, against which the inking roller bears, rotating as well as against the type or design on the cylinder, so as to ensure an unif-rm pressure. When in use the printing cylinder is passed once over the surface, to be marked so as to coll its spring, its revolution producing the desired impression, during which time the inking roller maintains a constant supply of ink to the type. The apparatus is then removed from the material, and the cylinder returns to its normal position by the uncoiling of the spring attached to its axis. A stop is provided on the cylinder, which comes in contact with the frame and limits the motion to one revolution in either direction. The inking roller consists of a hollow perforated cylinder covered with fiannel felt, or other suitable cylinder. This is filled with ink through an opening at one end; the ink passing through the perforations permeates the financi, and as the roller is rotated by the motion of the printing cylinder against which it bears, the type on the latter are kept continually supplied with ink. The indiarubber type may be readily detached from the printing cylinder and another substituted when required.—Patent completed.

2205 A. OLDHAM, Southport. Hanging pictures. Dated July 13, 1868.

An instrument is employed having at one end a swivel hook and at the other a screw hook, by which means the distance between the hooks may be made longer or shorter by turning the body of the instrument, so as to take in or let out the screw hook. By this means a picture frame may be raised or lowered for the purpose of adjustment with ease and certainty.—Patent abandoned.

2206 A. Munro and W. B. Adamson, Glasgow. Tools Dated July 13, 1868.

This relates to the application of chilled castiron as the material of which tools are made, such as are used for cutting, dressing, or finishing wood, metal, minerals, and fibrous substances, as well as for digging or cultivating land, including also hammers, picks, as well as tools of abrasion and penetration—Patent completed.

land, including also hammers, picks, as well as tools or abrasion and penetration—Patent completed.

2207 A. Munno and W. B. Adamson, Glasgow. Iron.
Dated July 13, 1868.

This consists as follows:—Chills of the shape required for the articles to be produced are provided, and molten crude or molten pig-iron is run into the chills. As soon as solidited, and for the purpose of making the material very hard and dense, the casting may be taken from the chill and cooled in water or otherwise, or it may be allowed to remain in the chills for a period, or the chills may be surrounded with, or cooled by, water. In place of forming the chill castings of absolutely crude iron, the iron before being cast may be partly refined by blowing atmospheric air into its mass, or by placing compounds of oxygen into the vessel or furnace wherein it is refined. It is to be clearly understood that the chills may be made of the finished shape of the articles to be produced, or they may different from the finished shape, and the castings made therein may be afterwards altered to the finished shape. The chilled castings are afterwards annealed or tempered, thus producing a material possessing many of the properties of wrought, forged, or malleable iron, but avoiding the coatly manufacture of iron now in use. The treatment hereinbefore set forth is especially applicable to

the construction of such articles as flyers for spinning machinery, buckles, stirrup irons, and light articles used in the arts and manufactures, which have hitherto been constructed of wrought iron, or forged of steel.—Patent completed

completed.

2208 G. B. MATHER, Wellingborough. Colour mills.
Dated July 13, 1868.

The matters are placed in a vessel, the lower portion of which opens into the smaller end of the internal cone, the axial line of which is in or about a horizontal position. Into this stationary conical surface is applied a corresponding conical surface, which is affixed to an exist which passes through a suitable opening provided for it in the side of the vessel, to be turned by a winch handle—Patent abandoned.

abandoned.

2209 G., G. W., and J. Betjeman, Pentonville. Book stides. Dated July 13, 1868.

To each of the slides a toothed rack is connected, which take into and receive motion from opposite sides of a toothed wheel mounted on a shaft or axis, to the outer end of which a knob is fixed. This shaft or axis is acted upon by a spring so as to keep the toothed wheel in gear with the racks, but when it is desired to allow the springs to act, the knob is pressed so as to throw the toothed wheel out of gear with the racks. A ratchet wheel and a catch or other suitable means are employed to retain the slides in any position to which they have been caused to travel.—Patent completed.

2210 W. R. Lake. Chancery-lane. Permonent serv. (A.

-Patent completed.

2210 W. R. LAKE, Chancery-lane. Permenent way. (A communication). Dated July 13, 1868.

This consists in the employment of ground plates of relied iron resting on a gravel bed, to which plates the rails are fastened. This can be done before leaving the rolling mill, or after the plates are in position. Cross pieces of iron rod are connected with the top rails by screw nuts and an ordinary "fish plate," where the rails join.—Patent completed.

join.—Patent completed.

2211 W. R. LAKE, Chancery-lane. Railway carriages. (A communication). Dated July 18, 1868.

The wheels of a railway carriage are connected in pairs by a hollow axle, through which passes a solid axle. The journals of this axle carry the weight. Secured to the carriage are two circular plates, which are firmly secured to the ends of the solid axle, and are each provided with a flange, which fits over a flange on the outer side of the wheels. The diameter of the flange of each plate is greater than that of the flange, to allow of considerable play between the two, the diameter of the solid axle being much less than that of the interior of the hollow axle, so that the former cannot come into contact with the latter. When the plate is in place upon the wheels, the flange touches another flange at one point only, to which point the weight of the load is transmitted from the axle through the plate, whereby a leverage is obtained equal to the distance from the centre of the solid axle to the point, and the amount of power required to move the load is thus correspondingly diminished.—Patent completed.

2212 J. C. LENER, Upper Thames-street. Railway

2212 J. C. LEVER, Upper Thames-street. Railway

2212 J. C. LEVER, Upper Thames-street. Railway sleepers. Dated July 14, 1863.

Bars of wood, iron, or other substance, as long as the width of the longitudinal sleeper, are employed, and are placed side by side. Sets of holes are bored through these bars in the direction of the length of the longitudinal sleeper, through which wires are placed so as to string the bars firmly together. At intervals, a bar is made long emough to be carried across from the sleeper of one line of rails to that of the other, so as to connect them; that is, at the intervals, one end of a long bar forms a part of the sleeper of one line of rails, and the other end forms a part of the sleeper of the other line of rails.—Patent abandoned.

2212 1 and 1 M TAYLOR Birkenhead. Promelling.

accanded.

2213 J. and J. M. TAYLOR, Birkenhead. Propelling.

Dated July 14, 1868.

For this purpose, portable paddle-wheels or screw propellers are so arranged as to be lowered in grooves fixed against the sides of the ship, and capable of being adjusted to any draught of water the ship may be taking.—Patent abandoned.

abandoned.

214 J. Baston, Shepherd's Bush. Bleaching. Dated July 14, 1868.

The material to be treated is first reduced by boiling and washing in the usual manner, as already well known and practiced by bleachers. When it has been sufficiently reduced, and the loose colouring matter removed, and the material brought to the state known as "boiled out," it is submitted, in a damp state, to the action of zone. It is then immersed in a chlorine bath of the ordinary character and strength, say from 1½deg. to 3deg. Twaddel, from about two to twelve hours (more or less). It is then removed and washed and soured in the usual manner, that is to say, it is washed and sterwards submitted to the action of an "antichlor," as well known and commonly practized. If the whole of the "sprit" is not "killed" or removed, or the desired colour or whiteness not obtained, it is again submitted, in a damp state, to the action of coone, and again washed and soured.—Patent completed.

2216 E. T. Kittor, Stratford. Fish size. Dated July 14, 2215 E. T. KITTOE, Stratford. Fish slice. Dated July 14,

1868.

The slice is formed in several parts, one of which is fixed to the handle, whilst the others are connected to the fixed portion of the slice by pin or other suitable joints. The movable parts are connected by links or connecting rods to a ring or slide capable of being moved to and fro along the handle of the slice.—Patent abandoned.

2216 J. BOOTH, Kingston-upon-Hull. Bone mill. Dated

July 14, 1868.

The grinding surface of this mill is composed of alter nate toothed rims and toothed grooves, combined with shellow cylinder or concave, having its internal concave surface formed with corresponding rims and grooves conversely arranged.—Patent abandoned.

versely arranged.—Patent abandoned.

2217 J. Cope and J. Bradbrook, Dalston. Bootbinding.
Dated July 14, 1868.

This relates to a machine for effecting the operation technically called "rounding," viz., forming the book round at the back, a process hitherto only accomplished by hand labour by a process of hammering. The machine consists of a movable vice, composed of two jaws, in which the books to be operated upon are securely held by their fore edges. The jaws are secured to a table. The table is provided on its under side with Vs, and is capable of being moved backwards and forwards on fixed horizontal guides of corresponding form. A reciprocating motion is communicated to their table by an adjustable crank, and on the back of a large bevel wheel, which is connected by a rod

to a similar pin on the under side of the table. The second part consists of an improved method of impressing the covers of books technically called "backing," and consists of a blocking press, having a rising block on which the book or cover to be operated upon is placed, a knuckle joint actuated by a cam through a connecting rod. When the knuckle joint is straightened, the bottom bed will be raised so as to give the impression. The third part of the invention relates to a machine for trimming the edges of books. This machine is provided with a revolving circular knife. The books are placed on the table, provided on its under side with V edges, which travel on rails, which may be of any convenient length, and have V grooves made therein. Any number of books may be placed on the table and secured by means of a screw clamp. When thus secured, they may be carried forward against the circular knife, which trims or cuts the edges. The books when trimmed are taken off on the other side of the cutter by an attendant, who then places on the table another lot of books, and when these latter are secured by the clamp, he reverses the action of the driving gear, and the table will be moved back, and the books thereby carried against the circular knife as before, and be out.—Patent completed. to a similar pin on the under side of the table. The s

2218 T. WOOD, Manchester. Railway signalling. Dated

back, and the books thereby carried against the dircular knife as before, and be out.—Patent completed.

2218 T. Wood, Manchester. Railway signalling. Dated July 11, 1868.

Each seat in the various compartments of a carriage is provided with a spring, which, when compressed, actuates a sliding bolt, key, or bar, placed underneath the body of the carriage, which is caused, when the spring is not compressed, to project outside the framework, in order to indicate the number of vacant seats inside the carriage. At each end of the carriage a glass door is provided, through which the guard of the train can enter; a mirror in the guard's box is so arranged that the entire length of the sompartment of the train is reflected therein, thereby giving the guard or passengers supervision throughout the train. Near the glass door a check string is provided, by means of which passengers may communicate direct with the guard. Another part of this invention relates to a novel arrangement of apparatus, whereby the passengers may communicate with the guard, in cases of great necestity, and the improvements consist in connecting tassels or handles projecting from the roof of the carriage, at short distances from each other, over the heads of the passengers, with a chain or rod, running over bowls inside the ventilator; these chains are connected with a lever and spring at each end of the carriage, which support a frame containing a half-moon shaped red glass, in connection with a lamp having a powerful reflector. When a passenger pulls down one of the handles or tassels, it withdraws the lever from under a red glass slide, allowing it to fall and expose a white glass; the same movement of the lever brings forward the light beneath a magnesium cap, which it ignites, and thus throws a brilliant white four bars, which embrace the ordinary draw bar; these bars and draw bars, projecting from the end of the carriage, are connected together by means of a plate, the opposite ends of the bars being connected to volute springs, situated bet

a supplementary book attached to the hook of the next carriage.—Patent completed.

2219 W. Shaw, Lancaster. Looms. Dated July 14, 1868. This consists, first, in the use of double-acting levers mounted on the loom frame, and reciprocating in opposite directions, which act in combination with a bowl mounted on a fixed stud on one of the levers, and which is caused to slide laterally by a lever motion, governed by the pattern chain, so as to bring the bowl in contact with one of two tappets of different diametes, which actuates the same, thereby giving movement to the double-acting levers and bars suspended therefrom, which are provided at their lower extremities with notches or teeth. During the contact of the bowl with either of the tappets, it is held or locked in position by means of a finger attached to the lever motion, which causes the lever bowl to slide, such finger being guided by a bar or pointer on either one of the the other side of it; the finger slides up and down, the locking bar or pointer being fixed to the frame of the loom. A second part consists in an improved construction and arrangement of the "box rod," the upper part of which is attached to the boxes as usual, but the lower part is provided with a series of teeth or notches, corresponding with the teeth or notches on the bottom, thus imparting the required rising and falling of the rods and the drop boxes connected therewith. A spring bolt entering one or the other of the series of notches formed on the box rod assists in retaining it at the different lifts, but giving may to its up-and-down motion when acted upon by the levers and rods.—Patent completed.

2220 W. B. FARWELL, New York. Heating ratheap carriages. Dated July 14, 1868.

2220 W. B. FARWELL, New York. Heating rathway arriages. Dated July 14, 1868.

This consists in fitting the connecting pipes between the arriages with a ball and socket joint, and fitting a pipe ree to slide in the connecting pipes to allow for the novements of the train. The pipes are supplied with team from the boiler to each carriage, a coil or series of ubes being placed under each seat for heating the compartment.—Patent completed.

partment.—Fatent completed.

2221 C. J. GALLOWAY and C. H. HOLT, Manchester.

Engines caives. Dated July 14. 1868.

These valves are formed with horns or projections which
are in width a little in excess of the space between them,
sufficient for the lap of the ports and the horns, and
consequently the spaces or ports of one piston valve are
opposite those of the other. The ports of one valve seat
are opposite the intermediate parts of the other valve seat.
Both piston valves are capable of rotation with their
shaft, which, whilst it is capable of sliding endwise, as
actuated by the eccentric, is also formed in part of a
hexagonal or other suitable figure, where it passes through

the boss of a tooth wheel, by which it is caused to rotate with that wheel, is taken into by the teeth of another wheel which the patentees prefer to be of half the diameter of the former; upon the axis of this second wheel, is applied a catch or star wheel adapted to be caught and successively moved for the rotation of the valves by a stud on a plate affixed to another axis, and this other axis also carries a mitre wheel, which, with another mitre wheel affixed to another axis receiving constant motion, are both simultaneously taken into by the teeth of an intermediate mitre wheel, which is capable of rotation on a rocking arm, actuated by the governor, so that whilst a constant rotary motion is being given to the valves the time in such rotation is varied by the action of the governor to regulate the cut-off—Patent completed.

2222 W. PATTON. Victoria-park. Breech-loaders. Dated

completed.

2222 W. Payton, Victoria-park. Breech-loaders. Dated July 14, 1868.

The barrel is formed to turn on an axis parallel or nearly so with the axis, and this axis, which is by preference affixed to the stock, is formed with a screw thread acting in a corresponding thread formed in the part carried by the barrel, so that in turning from the abutment portion, carried by the stock, it will travel outwards from such part of the stock to facilitate the clearance of the parts, also to facilitate the removal of spent cartridges.—Patent abandoned.

2223 J. THOMPSON and J. G. INGRAM, Hoxton. Feeding bottle caps. Dated July 14, 1868.

The cap is formed of india-rubber, moulded and vulcanized so that they will slip over and fit closely against the mouth of the bottle. In the centre of the top a hole is formed, through which is to be led the fiexible suction tube. A number of fine perforations, composed of three short straight slits radiating from a point, thus (Y), are formed through the cap, to allow of air entering: the bottle as fluid is withdrawn therefrom.—Patent completed.

2224 L. HANNART and N. A. AUBERTIN, Cheapside Door-picts. Dated July 14, 1868.

These improvements consist in taking a thin sheet of metal and cutting the letters entirely out by means of a rotating saw, or other cutting instrument, the plate being moved on a table in the direction of the shape of the letters, after which the plate so cut out is fixed to a plain piece of metal.—Patent abandoned.

plece of metal.—Patent abandoned.

2225 L. Hannart and N. A. Aubertin, Cheapside.

Type. Dated July 14, 1868.

This consists in making a long pattern in wood, or other
that several separate letters thereon, placed at
distances, as under, for the purposes hereafter stated.

The pattern is made in the form of a long trough, which,
when cast, is placed in a planing machine and the sides
planed true and to a gauge; this done, the casting is cut crossways by a circular saw, so as to separate the letters, which are
then ready to be set up by the printer, each piece being
as near as may be of the same size, so that when set up
they may present a flush surface.—Patent abandoned.

2226 H. LAWENGE, Durham. Mostag Awance berg.

they may present a flush surface.—Patent abandoned.

2226 H. LAWRENCE, Durham. Moving furnace bars.

Dated July 14, 1868.

The bars are caused to travel in one, two, or more endless chains or rows, and by alternately varying the speed
of each chain or row the sides of the bars are prevented
from being in continuous contact or maintaining the same
relative position one with the other during their movement from from to back of the furnace. Each bar or
alternate row of bars, as they pass over the several supporting rollers by which they are supported, are caused to
receive a slight lifting and lowering motion.—Patent
abandoned.

abandoned.

2227 A. TAYLOB, Birmingham. Spring studs. Dated May 15, 1868.

The studs are composed of a top and bottom part retained together by a concentric spring shank in the top part, passing down a concentric tube in the other part. When the two are put together, they will be so retained until relieved on the spring being pressed.—Patent abandoned.

doned.

2228 C. DE BERGUE and J. C. HADDAN, Westminster. Safes. Dated July 15, 1868.

The improvements comprised by the invention is the constructing strong rooms of thick iron or steel plates, so can be constructing strong rooms of thick iron or steel plates, so as can be constructed and relatively disposed as that with or without the interposition of wrought-iron flanged beams or girders, or of separate dowels or tongues between the plates, so as to afford a support and hold the plates together, without or with the additional hold or security which may be obtained from the simple bolting or keeping together of the parts. The patentees propose that the form of the safes be rectangular in either direction across the plan, circular, or elliptical. The several parts may be built up in their intended permanent position, and if desired within, or be afterwards surrounded by brickwork, masonry, or concrete, whereby the same may be rendered fireproof, and also additionally secure against the attempts of burglars.—Patent completed.

2229 W. HOLLINGWORTH and H. HALSTERD, Bradford.

2229 W. HOLLINGWORTH and H. HALSTRAD, Bradford.

9229 W. HOLLINGWORTH and H. HALSTRAD, Bradford. Supplying gas. Dated July 15, 1868.

A vessel is constructed to screw upon the end of the supply pipe of street lamps. It is set in a vertical position, and a pipe projects into the vessel so as to form an annular space or reservoir for holding mercury. A cap is formed with a cavity or projecting rim to enter the space and sink into the mercury in which the cap will float. The nipple or gas burner is fixed upon the top of the cap.—Patent abandoned.

2230 R. COUTY and J. RICHARD, Paris. Teaching singing. Dated July 15, 1868.

Dated July 15, 1868.

This invention is to facilitate vocal instruction at schools, and render the task less irksome by lessening the fatigue of the instructor, whose voice, after prolonged exercise, is not so likely to be in tune, and therefore unable to give the exact pith of the note desired to be sung it consists of an apparatus or rectangular box divided into three compartments. On the outer surface of the first of these a gamut or scale of do, re, mi, fa, soi, la, si, do, is printed; in the second, the notes or reeds, similar to those of an harmonium or accordion, are arranged; and the third constitutes the air chamber, which is put in communication with a bellows, by means of a fiexible tube.—Patent completed.

2231 R. CHAMBERLAIN, Eaton-source. Marticles.

2231 R. CHAMBERLAIN, Eaton-square. Morticing chies.
(A communication). Dated July 15, 1868.
The tool is formed with two side lips, bevelled at an angle of or about 45deg., with the face of the chiesl; the lips are devetalled inwards and upwards. The side fiaps,

which are also bevelled sufficiently to clear the sides of the mortice, project about one-eighth of an inch below the edge of the main bevel.—Patent abandoned.

edge of the main bevel.—Patent abandoned.

2232 J. H. JOHNSON, Lincoln's Inn-fields. Lamps. (A communication). Dated July 15, 1868.

This consists in making the whole of the body, stand, and burner, or wick holder of glass or any ceramic material in lieu of metal. Also in employing a cotton or other wick as an absorbent of the volatile oil introduced into the body, so that no free liquid will be contained therein, the vapour aloue emitted from the top of the wick being ignited, and hence liability to accidents from spilling the oil is greatly reduced.—Patent completed.

2233 J. BONNALL, Grantham. Seed drills. Dated July 15,

Springs are employed for chain drills to carry or act upon one set of the pulleys around which the chains which supply the corn, seed, or manure to the guide boxes pass. Also in the employment of a chain transversely of the machine for feeding the seed to the guide boxes, and in order that one or more of the guide boxes may be put out of action when desired, a series of slides are employed to shut off the communication between the seed box and the chain.—Patent abandoned.

chain.—Patent abandoned.

2234 T. Cook, Old Kent-road. Oil presses. Dated July 15, 1868.

This consists of a deep but narrow box with steamers, the entire width and depth of which is only the width of the cake after compression. To the bottom of the box a sliding or false bottom is arranged, as to be easily removed after the seed or other oil-yielding substance has been sufficiently compressed, to allow the compressed residuary matters or cake, to be forced by steam power out of the box into a receptacle below.—Patent abandoned. out of doned.

out of the box into a receptacle below.—Patent abandoned.

2235 W. TURNER, Blackburn. Pump buckets. Dated July 15, 1868.

This consists in a novel construction of the bucket and packing and in the use of india-rubber for keeping the packing at a uniform tightness, and preventing excessive friction. The packing consists of an outer metallic ring, having an internal flange supported by the botton plate of the body of the bucket, the ring and flange being at one part cut entirely through or split vertically, and the flange at several parts, as far as the inner surface of the ring. Upon this flange, between the ring and the body of the bucket, one or more rings of india-rubber are placed, upon which a flat metallic ring bears, which acts as a washer, and on the top plate of the bucket there are screws which, when turned in one direction, act on the flat ring, and press upon the india-rubber, which expands and presses the outer metallic ring against the cylinder or barrel, and maintains a liquid-tight packing without undue friction. The pressure of the screw is exerted on the india-rubber after the bucket is placed in the barrel or cylinder, and if the pressure is properly adjusted at first, the elasticity of the india-rubber causes the outer metallic ring to follow up the wear and keep the packing tight without frequent turning of the screws.—Patent completed.

2236 J. I. MAGFARLANE, Upper Holloway. Shirt fronts.

2236 J. L. MAGRARLANE, Upper Holloway. Shirt fronts.
Dated July 16, 1868.
This consists in introducing in the centre of the front, either by weaving or by other means, a representation of a cravat or tie.—Patent abandoned.

a cravat or us.—Fatent abandoned.

2237 R. WHISTON, Wolverhampton. Sash fastener.

Dated July 16, 1868.

This fastener is so constructed that when the arm is pressed into its position for holding the sashes together, it shall firmly lock itself underneath and against the plate on one side, and in a notch in the catch plate on the opposite side.—Patent abandoned.

site side.—Patent abandoned.

2238 H. W. RIPLEY and T. SHACKLETON, Bradford Winding threads. Dated July 16, 1868.

This invention consists in winding printed or other warps or threads of cotton, or other fibrous substances, in single or double ends from a beam or large bobbin on to or upon a series of small bobbins, spools, or tubes. These may be driven by frictional contact with pulleys or other means, and traverse motion may be given to a series of guide eyes for guiding the ends to the bobbins in regular order.—Patent completed.

2239 R. Berson, Edgware-road. Boiler. Dated July 16.

1868.
This consists of a boiler of cylindrical form so constructed that the heat from charcoal can be made to impling upon a large surface and heat the contents quickly. Also in a rotary bellows worked by a weight and cord.—Patent abandoned.

2240 T. F. G. WINTOUR, Kentish Town. Ventilating. Dated July 16, 1868.

Dated July 16, 1868.

The apparatus consists principally of a rectangular box or frame fitted with a wire gauze screen and a sliding glass shutter. The screen is folded backwards and forwards horizontally in a zig-zag or serpentine form, and the glass shutter slides vertically in contact with the inner edges of these horizontal folds, which are all in the same vertical line, so that as the sliding shutter is lowered it opens up each fold successively.—Patent abandoned.

2241 D. RUSSELL, Camberwell. Masting ships. Dated July 16, 1868.

The masts are so constructed that they can be lowered

when desired, as, for instance, when steaming against the wind. For this purpose, in lieu of the ordinary lower mast, a pair of shear legs, hollow or solid, is employed, the lower ends of the shears being respectively secured at the port and starboard sides of the vessel, where their feet are bolted or hinged in troughs or shoes.—Patent abandoned.

2242 J. C. RAMSDEN, Bradford. Looms. Dated July 16,

1868.
This relates to a peculiar and novel method of forming the shed required in weaving that class of goods in which spots or figures of either a different colour or material to the ground weft are inserted, whereby a figure containing plain cloth can be woven within the outlines without losing a ground pick, and this is accomplished somewhat as follows:—Both healds or heddles are employed, and a common jacquard apparatus so arranged that when the jacquard is in operation the warp threads are free to work up and down in the healds without any strain being placed thereon, and when the healds are in operation the warp threads are free to move up and down in the harness without any strain.—Patent abandoned.

2243 W. R. LAKE, Chancery-lane. Straw cutter. (A communication). Dated July 16, 1888.
This consists in the peculiar combination of a cutting blade or knife with two handles, one of which is formed or fixed at the extremity of a rod or stem, which carries the knife, while the other handle projects at right angles from the said rod.—Patent completed.

from the said rod.—Patent completed.

2244 W. R. Lake, Chancery-lane. Harness links. (A communication). Dated July 16, 1868.

This consists partly in the peculiar mode of constructing links or rings with a split or opening, which allows such links or rings to be conveniently connected or disconnected with other links or couplings, but will not allow them to become accidentally detached or removed from the same. The invention also consists partly in the combination of a split or divided link or ring, with a tongue or catch to form a buckle for securing the link upon the reins or other parts of harness, or to straps and bands for other purposes. The links or couplings are formed of wire, which is bent and twisted into the required shape. The two ends of the wire are flattened and lapped over each other, the split or division being between them. The split or division is widened at the exterior of the link, to facilitate the insertion therein of any article to which the link is to be united.—Patent completed.

2245 S. DAVIS, Strand. Animal clipper. Dated July 16,

2245 S. DAVIS, Strand. Animal clipper. Dated July 16,

1868.
A series of comb teeth are formed upon the front end of a plate or frame, which teeth serve to collect the hair or wool to be cut between them, the edges of the teeth acting as blades, against which the hair is cut, when the movable cutter (mounted upon a centre at the back part of the comb blade or frame) is moved across the surface of the comb by the operator.—Patent abandoned.

### APPLICATIONS FOR LETTERS PATENT.

Dated January 19, 1869.

167 S. G. Archibald, Edinburgh. Improved machinery for cleaning boots and shoes, knives, forks, spoons, and other articles, and for sharpening knives and other cutting

other articles, and for sharpening knives and other cutting instruments.

163 M. Burke, Liverpool. Improvements in the construction of ships' skylights.

169 G. Lowry, Bury-street Foundry, Salford, Lancashire. Improvements in the construction of hackling machines.

170 W. and J. Pain, Charles-street, Stepney, Middlesex. An improved floor dog or flooring cramp.

171 H. W. Hammond, Princess-street, Manchester. Improvements in the mode of, and in apparatus or mechanism for, driving piles. (A communication).

172 J. Armstrong, Brinsworth Iron Works, Masbro', near Rotherham, Yorkshire. Improvements in crossings and switch apparatus to be used with the permanent way of railways, part of which improvements is applicable to other purposes.

other purposes. other purposes. 173 C. Baunscheidt, Endenich, near Bonn, Prussia. A new or improved instrument to be used in the treatment

A new or improved instrument to be used in the treatment of rheumatism and other diseases.

174 N. D. Spartali, Liverpool. An improved mode of, and apparatus for, propelling vessels.

175 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in wheels for railway carriages, locomotives, and other vehicles. (A communication).

176 C. E. Brooman, Fleet-street, City, patent agent, Improvements in breech-loading guns. (A communication).

Improvements in breech-loading guns. (A communication).

Dated January 20, 1869.

177 G. A. Crow, Newcastle-on-Tyne. Improvements in radial and other drilling machines.

178 J. Siddeley and F. N. Mackay, Liverpool. Improvements in means and apparatus for cooling, refrigerating, and ice making.

179 F. A. Paget, Seymour Chambers, York-buildings, Adelphi, W.O. Improvements in the construction and arrangement of steam bollers, and in their furnaces, grates, and flues. (A communication).

180 W. Gillett and C. Bland, Croylon, Surrey. Improvements in mechanism for bell and clock chimes, such improvements being also applicable to keyed automatic or other musical instruments.

181 J. Edwards, Richmond-road, Hackney, Middlesex. Improvements in communication between passengers and guards of railway trains, and signalling on railways.

182 E. Burton, Upper Clapton, Middlesex. A new or improved machine for distributing sand or other matters in public thoroughfares.

183 E. Barcroft, Rawtenstall, Lancashire. Improvements in the construction of cocks, taps, or valves for controlling the flow of water or other liquids.

184 P. C. Evans, Brimscombe Mills, Gloucestershire, and H. J. H. Kling, Glasgow. Improvements in apparatus for feeding wool or other fibrous materials to carding or other machines.

185 M. J. Matthews, Glasgow. Improvements in harmoniums.

moniums.

monlums.

186 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in the manufacture of illuminating gas and of sponge, by the action of hydrocarbon liquids or fluids on metallic ores, and in the furnaces for melting said sponge and other metals. (A communication).

187 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in metallic action frames for pianofortes. (A communication).

188 F. Lipscombe, Strand. Improvements in purifying and storing water, and in the apparatus employed thervin.

189 C. de Bergue and C. Faure, Strand. Improvements in locomotives and other raliway carriages.

190 D. Spooner, West Abbey-road, Kilburn, Middlesex. An improvement in the construction of mills for cleaning rice or other grain.

Dated January 21, 1869.

191 J. W. Wilson, Barnsley, Yorkshire. Improvements in steam boilers.

192 J. C. L. Camel, Rue St. Helene, Lyons, France. An improved surgical truss or bandago.

193 D. Rivenc, Geneva, Switzerland. Improvements in apparatus for mending and cutting or shaping millstones.

194 A. M. Clark, Chancery-lane. Improvements in clasps or fastenings for scarfs and other articles of dress. (A communication).

195 C. J. Clubb, Endsleigh-street, Tavistock-square, Middlesex. Improvements in drills and apparatus for boring holes in coal, hard ground, slate, and minerals. 186 H. A. Bonneville, Sackville-street, Piccadilly. Im

196 T.C. Lewis, Shepherd's-lane, Brixton, Surrey. The improvement of steam engines.
197 C. G. Gumpel, Leicester-square, Middlesex. Improvements applicable to keyhole plates and escutcheons.
198 F. Walton, Staines, Middlesex. Improvements is the manufacture of artificial marble.
199 W. R. Lake, Southampton-buildir lane. An improved apparatus for sheari akins. (A communication).

Dated January 22, 1869.
200 B. Baxenden and J. Heald, Chorley, Lancashire, Improvements in looms for weaving.
201 A. B. Cunningham, Royal Military Academy, Woolwich. Improvements in apparatus for throwing horses and other cattle for veterinary purposes.
202 B. Craig, Branthwaite, Cumberland. Improvements in apparatus or machinery for communicating and signaling between passengers, guards, and drivers of railway trains.

ling between passengers, guards, and drivers of railway trains.

203 M. Tildesley, Willenhall, Staffordshire. An improvement or improvements in the manufacture of the annealing cans used in annealing sheet iron.

204 J. Wilkins, Nottingham. Improvements in the manufacture of looped and knitted fabrics.

205 J. Speight, J. E. Burton, and E. Brooke, Bradford, Yorkshire. Improvements in machinery or apparatus for spinning, twisting, or doubling and roving wool or other fibrous substances.

206 A. Maw, Benthall Works, near Broseley, Salop. Improvements in the construction of moulds for moulding china, earthenware, or pottery.

207 F. R. Ensor, Park, Nottingham. Improvements in the manufacture of the fabric known as Ensor net for lace.

lace.

208 T. Cook, Old Kent-road, Surrey, and J. Watson, Victoria Chambers, Westminster. Improvements in the mode of, and apparatus for, producing and applying motive power, also applicable for measuring the flow of gas and other fluids.

209 J. W. and J. W. Horsfield, Vulcan Iron Works, Dewsbury, Yorkshire. Improvements in steam boilers.

210 W. E. Gedge, Wellington-street, Strand. Improvements in machines for cutting into slate in quarries, applicable also to machines for cutting in coal pits, mines, and stone quarries. (A communication).

ments in machines for cutting into slate in quarries, applicable also to machines for cutting in coal pits, mimes, and stone quarries. (A communication).

211 W. Dennis, Aldermanbury, City. Improvements in letter boxes, letter pillars, and such like depositories.

212 W. Burgess, Newgate-street, City. Improvements in mineing machines.

213 J. Beattie, Surbiton, Surrey. Improvements in buffing apparatus for railway carriages.

Dated January 22, 1869.

214 J. Millward, Birmingham. Improvements in machines for quarrying and aswing stone or minerals. (A communication).

215 J. Ortton, Courland-grove, Wandsworth-road, Surrey. Improvements in graduating the admission of steam to the cylinders of locomotive and other ateam engines by means of the reversing and regulator gearing. (A communication).

216 E. Simons, Sheffield. Improved means of communicating between passengers, guard, and engine driver upon railway trains.

217 W. Huggins, Halstead, Essex, and H. Horsnaill, Bulford Mills, near Witham, Essex. Improvements in dressing millstones, and in apparatus to be used therefor. 218 L. J. Crossley and R. Hansom, Halifax, Yorkshire. Improvements in the means used in steaming printed yarns.

219 H. H. Murdoch, Staple lun. Improvements in the

218 L. J. Crossley and R. Hansom, Halifax, Yorkshire, Improvements in the means used in steaming printed yarns.
219 H. H. Murdoch, Staple lun. Improvements in the smelting of copper, and in apparatus to be used therein, (A communication).
220 B. Mountain, T. Richmond, and G. Duffield, Leeds, Improved appliances to be used in the manufacture of boots and shoes.
221 J. Dinsdale, Skipton, Yorkshire. Improvements in spinning and twisting machinery.
Dated January 25, 1869
222 J. M. Merrick, jun., Massachusetts, U.S.A. A composition or compound, and a mode or process of treating and moulding the same (such compound being for various useful purposes in the arts or for the manufacture of various useful purposes in the arts or for the manufacture of various useful or ornamental articles).
223 W. M. Welling, New York, U.S.A. Improvements in compositions resembling ivory.
224 C. Toucherleux, Rue Ste. Appoline, Parls. Improvements in hinges of ear-rings, applicable also to certain other articles of jewellery.
225 C. B. Parkinson, A. and J. Metcalfe, and W. H. Heald, Preston, Lancashire. Improvements in the construction of mules for spinning.
226 R. G. Lowndes, Auldhousefeld and Crofthead, Renfrewshire, and M. M. Callum, Barrhead, Renfrewshire. Improvements in machinery or apparatus to be employed for finishing textile or other fabrics.
227 C. E. Brooman, Fleet-street, City, patent agent. Improvements in the construction of cocks or valves. (A communication).

Improvements in the construction of cocks or valves. (A communication).
228 W. E. Newton, Chancery-lane. Improvements in machinery for stamping and forming articles of sheet metal. (A communication).
229 J. Carr, Manchester. Improvements in the production of tapes or ladders for venetian blinds.
230 A. V. Newton, Chancery-lane. An improvement in fermenting substances and germinating grain and seeds. (A communication).
231 E. Hartley, Oldham, Lancashire. Improvements in looms for weaving.
232 H. D. Bowyer, Ripley, Woking, Surrey. Improvements in the manufacture of wheaten flour.
233 R. J. Green, Birmingham. Improvements in collar studs or buttons, shirt studs, sleeve links, and other like articles.

articles.
234 J. and S. Roberts, West Bromwich, Staffordshire. Improvements in the manufacture of moulds for casting, and in machinery or apparatus to be employed in the said

and in machinery or apparatus to be employed in the said manufacture.

235 H. W. and R. Lafferty, Gloucester, Camden, New Jersey, U.S.A. New and useful improvements in centri-fugal machines for draining sugars and other substances, and in the manner of their support, and the means of communicating motion thereto.

Gold, Silver, and Refiners' Pots.

THE ONLY SILVER MEDAL awarded to Plumbago Crucibles for superior Quality and Durability by the Jury who tested and proved the Crucibles of all British Exhibitors in Melting Steel, Malleable Iron. Copper, Brass, &c., &c., also Diploma and Certificate of Superiority from the Secretary of the Jury, having been given to, and received by, JOHN HYNAM, he cautions all Exporters and Consumers of Crucibles against the praudulent statements of unprincipled Manufacturers who may represent themselves by circular, advertisement, or any other means, as having been awarded any Medal for Crucibles whatever, by, or with the knowledge or consent of, the Jury who tested and proved this is the Certificate given voluntarily by the Secretary of the Jury; it speaks for itself.

Certificate of Superiority received from the Secretary of the Jury.

Mr. Hynam. Sit.—On my return to Paris after a long absence, I have again taken up your claim as regards the Awards. I am happy to inform you that you have gained the First-Class Silver Medal for your Crucibles in Class 40, and that through a mistake your name does not appear amongst the medals of that class. I have all the more pleasure in apprising you of this good news, since I have been able to appreciate the superiority of your productions, tested and proved by me in the laboratory of the Exhibition Universal.

Legrander Legrander Crucibles in Class 40, and that through a mistake your name does not appear amongst the medals of that class. I have all the more pleasure in apprising you of this good news, since I have been able to appreciate the superiority of your productions, tested and proved by me in the laboratory of the Exhibition Universal.

Legrander Crucibles in Class 51.

Legrander Crucibles and Durables and Durable Crucibles and Durable Crucib

nguished consideration.

L. GRANDEAU, Socretary of the Jury.

The GRAPHITE PLUMBAGO CRUCIBLES manufactured by J. HYNAM are in general use in the Royal Arsenals and Dockyards of Great Britain, the Imperial Mint at Paris, the Imperial Arsenals and Dockyards of France, where their durability in the melting of Steel (for which Crucibles are specially made) has been proved at least 30 per cent. superior to all other Plumbago Crucibles previously used by the French Government. The most celebrated Engineers, Founders of Steel, Malleable Iron, Copper, Brass, &c., &c., Gold and Silver Refiners, Melters, and Manufacturers of every description of Metal in all parts of the World have found the GRAPHITE PLUMBAGO CRUCIBLES manufactured by J. HYNAM (after a fair honest trial side by side in their furnaces with the Crucibles of all other manufacturers) to be superior in economy, non-absorption of Metal, freedom from cracking or splitting and durability, to every other description of Plumbago Orucibles at present known. Crucibles are made specially for Steel, Malleable Iron, Copper, Brass, Zinc, Antimony, Gold, Silver, &c., &c., of every shape and size required.

J. HYNAM respectfully requests the attention of all Exporters and Consumers of Crucibles to the above important facts.

Price Lists, Testimonials, &c., &c., forwarded immediately upon application to

# WAYGOOD'S PATENT DONKEY PUMP

OR IMPROVED BOILER FEEDER AND INJECTOR.

The numerous articles of this kind now offered proves their great utility. Amongst the various competitors for public patronage, we claim many advantages over most of the others, for the following reasons:—The first is its extreme simplicity; next, it is a well-known fact that steam pumps with small flywheels must of necessity act very rapidly, in order to obtain a sufficient amount of centrifugal force in the wheels to keep themselves going; this rapidity provents them from properly filling the barrel; the plunger thus also on a partial vacuum, which tends to loss of power and self destruction. Neither with so short a stroke can water be brought from any depth. The improved one which we now offer, and which is represented in the sketch, has no flywheel, and has a stroke of fully double the usual length; this enables them to bring the water up 20ft, if required. It works most effectively at from 30 to 60 strokes per minute; the barrel thus fills at every stroke, and delivers its charge into the boiler with great regularity, under any pressure, from 6th, to the inch up to 150. The small quantity of steam it consumes is surprising. Any Pump not found to answer the description above given can be returned after a month's trial.

Any number of Testimoniais can be given. They have been alopted at the Woolwich Arsenal, where they give perfect satisfaction.

# MECHANICS' MAGAZINE.

LONDON: FRIDAY, FEBRUARY 5, 1869.

ATMOSPHERIC TRAIN SIGNALLING BOUT nine months since we noticed a A BOUT nine munus since " yestem of very simple and efficient system of principle. telegraphy upon the atmospheric principle, which had been perfected by Messrs Wier. This system will have become familiar to many of our readers from its adaptation on board the "Bellerophon," the ships which laid the Malta and Alexandria telegraph cable, and other vessels. It is, however, its application in another direction with which we now have to deal—namely, as a means of communication between passengers and guards in railway trains. At the present time, the railway companies are on the alert to satisfy he requirements of the recent Act of Parliament, which directs the adoption of a means of communication in trains. With this view. a trial of Messrs. Wier's system was made on Saturday last on the London and South Western Railway. The trial was conducted by Sir Samuel Canning, and Colonel Yolland represented the Board of Trade. There were also present Mr. Beattie, the locomotive engineer, and Mr. Williams, the superintendent of the South-Western Railway, Mr. Seymour Clarke, of the Great Northern, Mr. Martley, of the London, Chatham, and Dover, Mr. Ray, of the London and Brighton, and other gentlemen representing various railways.

Messrs. Wier's system of atmospheric telegraph consists mainly of elastic metallic airtight vessels, and which are far superior to those of india-rubber that have been introduced in other systems. These vessels are corrugated, and are similar to those used in aneroid barometers. Three of these chambers, each 7in. in diameter and 1in. in depth, are fixed over each carriage, communication being effected from one carriage to the other, and so on, to the front and rear guards' vans, by tubing of small diameter. Soft metal tubing of 1-8th inch internal diameter is used on the carriages, the unions being of india-rubber tubing, and the junctions or couplings between the carriages of brass. These couplings are very ingenious. A couple of thumbscrews, on being turned round, re-lease the coupling, and at the same time shut off communication with the atmosphere. In each of the guards' vans is an air chamber of smaller dimensions than those on the carriages, being only 3in. in diameter, and  $\frac{1}{4}$ in. in depth. It therefore follows that on compressing any of the larger chambers the smaller one will be distended, communication of course being perfect. The distension of the chamber in the guard's van causes it to act upon a train of clockwork, which strikes an alarum and gives the necessary intimation to the guard that he is required by a pasenger. The guard then signals to the driver at least such was the arrangement on Saturday-although the system allows of direct communication with the driver, if it is found The signal is made from the carriage by means of a bell-pull connected with a lever on the roof, which compresses the air chambers, and at the same time releases a semaphore arm at the end of the carriage, which at once indicates the point from whence the signal was given. The compartment from which the signal was made is easily known by the bell-pull remaining down until the guard releases the lever and restores the semaphore to its normal position.

A train of twenty-five carriages, measuring bout 600ft. in length, and fitted with this imple apparatus, made a run to Woking and

back, upon the occasion in question, with the most successful results. Signals were given from a carriage near the centre of the train, at irregular intervals of time, and were received on the footplate of the engine practically instantaneously, although they were communicated through the guard. This was ascertained by Colonel Yolland and the gentlemen who signalled having acceptance in the control of the con tleman who signalled having compared time at starting and their notes on stopping, the Colonel having travelled on the footplate. The train was stopped at Kingston on the way down, and shunted on to a siding, where a carriage was taken out of the train in order to show the facility with which such an operation could be conducted. The connection is so constructed, as already explained, that it is severed and reunited with equal facility, so that no loss of time can occur in this respect, either in making up a train or There was also a modificataking it apart. tion of the system shown, by which one guard was enabled to talk either with another guard or with the driver. This result depends on the number of thrusts given to the air-chamber in one guard's van, and which, acting on the chamber in the other van, caused a hammer to strike a bell. Thus, by forming an alphabetical code, messages might be transmitted with ease and certainty. There are, of course, various other points of detail which occur in practice in the working of trains, and for which provision could readily be made under Messrs. Wier's system. We have only described its application upon an experimental train, in which there was no necessity for considering or providing against the exigencies of regular train service. cient, however, was done to impress all present with the simplicity and the practical character of the system, and to show that the details could be readily arranged to suit the varying requirements of different railways. As the adoption of any system by railway companies will doubtless be governed first by its efficiency and next by its cost, we think it right here to mention that the trials of Saturday fully satisfied us that no objection can be raised to the Wier system on the first point, whilst its extreme simplicity, and the absence of any parts susceptible of wear and tear, indicate economy both in first cost and in maintenance. This can be readily proved by an examination of the system at the offices of the patentees, 10, Philpot-lane, Fenchurch-street, City. We may add that Fenchurch-street, City. We may add that the "Great Eastern" is now being fitted with this atmospheric telegraph, preparatory to laying the French cable. For such pur-poses, Sir Samuel Canning stated he has found it invaluable.

## THE BRITISH INDIAN SUBMARINE TELEGRAPH COMPANY.

T is but a few days since we referred to the probable telegraphic extensions of the year, and, amongst those extensions, to a new link in the chain of communication between England and our East Indian possessions. We certainly looked forward to it as being one of the early projects of the year, but did not expect the advent of such a scheme so soon after our remarks. The past week has seen the prospectus of the British Indian Submarine Telegraph Company, and before these remarks are before our readers, the share application list will have closed.

When the Anglo-Mediterranean Telegraph Company was formed for laying a submarine cable direct from Malta to Alexandria, it was in contemplation, on the success of that line, to extend the telegraphic system to Aden and The successful submersion during Bombay. the past year of the Mediterranean cable, and the amount of traffic carried through it, has justified the present line in being brought out "in connection with the Anglo-Mediterranean telegraph."

India has not been without its lesson. The original attempt of laying a submarine cable to India proved a costly flasco. Since then, we have learnt experience. It is idle here to rake up the old story of the Red Sea cable; it may be summed up in a few words,—a bad So much route and an unsuitable cable. agitation had been got up at different times amongst those specially engaged in Indian business, that, at the last, a Parliamentary enquiry sat in 1866 to investigate the postal and telegraphic service to India. The committee, over which Mr. Craufurd presided as chairman, were decidedly in favour of a telegraphic route via Suez and Aden to Bombay. A scheme for the furtherance of this object came out in 1867, but it is not to be wondered at that, as a result of the money panic, there was a general want of confidence in everything monetary, and the scheme died. Since that time, the wonderful success of the Atlantic cable revived confidence in deep sea telegraphy, and the question was again brought forward. The further success of deep sea telegraphy, in the laying of the Malta-Alexandria direct submarine cable, has made the extension of telegraphy by submarine cable to India a necessity. Having got so far as Egypt, it would not do to stop there.

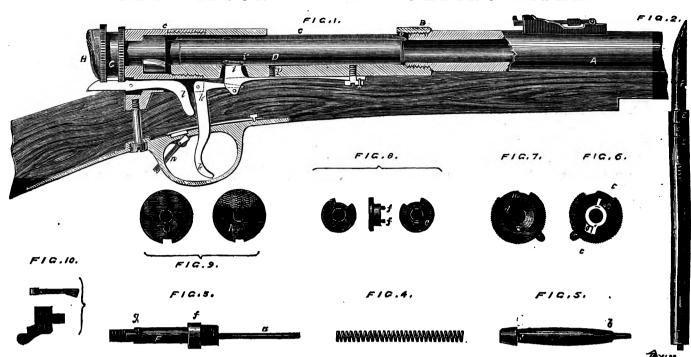

By the assistance of the Government, careful soundings have been taken, so that an accurate knowledge is now obtained of the bottom of the Red Sea and the Indian Ocean; and lately the "Admiralty has recently obtained an excellent line of soundings from Aden to Bombay, indicating low temperature, and that the nature of the sea bottom and the depths of water are similar to those of the present Atlantic submarine cable route, and the soundings in the Red Sea previously taken furnish a safe and satisfactory line." The prospectus informs us that the company has been incorporated for the purpose of constructing a submarine telegraph line between Suez, Aden, and Bombay, so as to complete a direct and reliable line of telegraphic communication between Europe and India, and with a view to future extension to China and Australia." Our present system of communication with Egypt is as follows:—Telegrams leaving England are usually forwarded by the submarine cable to France — through France they proceed to Susa, on the Franco-Italian frontier, from which point they are transmitted over a line belonging to the Anglo-Mediterranean Company to Modica in Sicily, and over the Medi-terranean Extension Company's cable to Malta, from there over the Anglo-Mediterranean Company's cable to Alexandria, and then again over a leased English line to So, in fact, with the exception of the French portion, the route is entirely English. We naturally have some pride in our English telegraphists, and it is always with additional confidence we send messages by means of English operators. The route augurs well both for speed and, what is really more necessary, accuracy; this, it may be assumed, there is a greater chance of obtaining when the message passes all the way through the hands of an operator who speaks a similar language.

The British Indian Company have entered into a provisional contract with the Telegraph Construction and Maintenance Company for "constructing a thoroughly efficient cable— 3,600 nautical miles in length—and for laying the same." The contract includes stations, station requisites, and instruments for working the traffic, and the contractors are to hand over the steam-ship "Chiltern," with all her "cable fittings, and machinery, as a maintenance ship." The capacity of the cable is guaranteed by the contractors at not less than twelve words per minute. The capital of the company is £1,200,000, and the contract price is £1,000,000, of which sum £540,000 is to be paid in cash, and £460,000 nean telegraph."

in fully paid up shares. Of this latter
The history of our submarine lines to amount, £150,000 is reserved, and not to be

Digitized by GOGIC

# THE WILSON BREECH-LOADING RIFLE.

paid over, as to £50,000, until the cable is successfully laid between Suez and Aden, and as to the remaining £100,000 until the line has been completed between Aden and Bombay. Of the remaining shares, £380,000 have been taken, leaving £170,000 for public allotment; to the holders of these several amounts, a number of free shares (£137,500) are to be allotted as profit shares, the balance of the capital being put down to expenses, &c. With a company brought out under such terms, and with so little share capital to be taken, it is difficult to imagine anything but success; and by this time we may suppose the whole thing completed. According to the contract, the work is to be completed by April, 1870, and from what we know of the capabilities of the contractors, the time does not seem long.

Although the cable is of so great a length,

it will not require the large size of core hitherto generally adopted in a long submarine cable. The use of Thomson's reflecting galvanometer as a receiving instrument is a new era in submarine telegraphy, and from the experience gained from working with that invaluable instrument on the Atlantic and Malta and Alexandria cables, it is found that a smaller quantity of copper and guttapercha are required than for the ordinary working by the Morse instrument. The core of this cable will be, therefore, smaller than might be expected, and a consequent economy effected. It is with pleasure that one point can be singled out in the new scheme—that the lessons taught by experience, though thrown away upon some companies, are not so with the projectors of the present. The interruptions on our English cable, on the old Malta and Alexandria, in the Persian Gulf line, have proved indubitably the wise policy of a maintenance steamer, fitted with every necessary for undertaking any repairs. In the contract with the Maintenance Company, the British Indian Company take over their repairing ship, the "Chiltern." Should the line be laid, the vessel will always be there to repair any damage, though we must, in the interests of telegraphy, trust that

# THE WILSON BREECH-LOADING RIFLE.

it may be long before her services are required.

THE construction of breech-loaders upon the bolt system has received various practical illustrations at the hands of inven-

tors in this direction. The most prominent of these has been Mr. Wilson, who has spared neither time nor expense in rendering his gun the most perfect of the class it ably represents. The merits of this arm were made manifest on Friday last, the 29th ult., when a very interesting and satisfactory trial took place at the shooting range, Wormwood Scrubbs, in the presence of a number of distinguished officers and other gentlemen who met, at the invitation of the proprietors of the system, to witness the experiments. Amongst the company, we noticed General Sir Gaspard le Marchant, Gen. Boileau, R.E.; Captain O'Hea, Captain Le Marchant, Mr. O'Beirne, M.P.; M. Mariatini, the Greek Consul-general; General Hadji Shaw, of the Persian Legation; the Spanish Consul, Senor Bulleras; Senor Ponce de Leon, and other Spanish gentlemen; Mr. J. E. Barnett, Mr. Latham, Mr. P. Le Neve Foster, Mr. Casey, &c., &c. Before describing the rifle and giving the particulars of the trials, it may be as well to refer to some circumstances connected with the history of this arm.

It appears that an earlier model of the rifle (but without the recent improvements) was, some time since, after repeated solicitations from the Sub-Committee on Small Arms, at Woolwich, left there for examination and experiment. Either through negligence on the part of the Committee, or some other unexplained cause, Mr. Wilson was not permitted to be at the trials, nor even allowed the opportunity of examining his gunand pronouncing its mechanism correctly assembled previously to the experiments, although it had been several times stripped and distributed for examination while in the hands of the Committee. Under any cir cumstances, we should consider such a course on the part of a committee highly improper and reprehensible, whether regard be had to its own position and safety, or to the rights and interests of the inventor. In the present case, however, it is peculiarly so, inasmuch as on the trial of the gun, a mishap occurred, which may have been due to this very negligence of the Committee in not assuring itself that the gun was correctly assembled before commencing the trials, but which may also have been, and most probably was, due to a faulty cartridge, or a too sensitive or projecting cap. However this may be, it seems that the Committee, without stopping for reflection and fair examina-

tion, at once (and we think unjustly) credited the mishap to the system, without any reference to the more probable cause of the mishap—namely, the cartridge, although it is notorious that numbers of mishaps have before occurred with other guns from this cause. We mention these facts in the interest of inventors and the public generally, and because we consider it unfair that the public should be invited by advertisement, and solicited by committees, to submit to their fair and impartial examination the produce of its brains and po ket, and that when the moment for trial arrives, it should be practically ignored, and its property injured and denounced without a hearing. It is no wonder, in view of such circu matances, that the public is growing wary of Government advertisements and invention committees, and more especially when such committees avail themselves of the ideas and experiences furnished by the public, to concoct some invention of their own, to the prejudice and injury of those they have invited to serve them. It was under these circumstances, and because it is felt that obstacles have been thrown in the way of a fair trial of the Wilson gun at Woolwich, and thereby injustice done to a really valuable invention, that the proprietors of the system wisely determined to submit it to a public test, which, as already observed, took place on this day week. The construction of the Wilson rife will be seen from our engraving, to which the following description refers.

In our engraving, fig. 1 is a longitudinal sectional view of a portion of the Wilson rifle, the breech chamber being shown closed for discharge; A is the barrel, B is the breech shoe which is screwed upon the barrel, C is the shoe cap, which is case-hardened and screwed upon the shoe. The cap is formed with openings to allow the lugs on the locking handle to pass through and interlock with the cap, as seen in the engraving. D is the breech bolt which slides in the shoe B, and which is made hollow to contain the strike and its spring, as seen at fig. 2, which show an under side view of the bolt. E is the breech bolt end-piece, screwed into the place of the shank F forming a centre on which the locking handle partially rotates when the locking handle partially rotates when the strike is end-piece is shown at fig. 3. Fig. 3 shows the spiral spring which actuates the striker, fig. 5, and which is guided in

Digitized by Google

action upon the rod a, fig. 3. The striker. fig. 5, is made of steel, and partially hollowed out for the spring, fig. 4, to work in, by which arrangement the advantage of a long and strong spring is secured. The striking point b is screwed into the body of the striker, and can be conveniently replaced, if broken.
The rear of the striker is shouldered and undercut at b<sup>1</sup>; on closing the breech bolt, this part engages with the head of the spring i, fig. 1, at the point i, which causes the compression of the spiral spring, fig. 4, on the breech being completely closed. On pulling the trigger, the spring is disengaged from the striker, and the striker is projected forward against the cap of the cartridge, and thus discharges the gun. G, fig. 1, is the locking handle, which is thoroughly case-hardened like the shoe cap in which it interlocks, a front end view of which is seen at fig. 6, c c being the locking lugs. Fig. 7 is a rear end view of fig. 6, showing the part d in which the spring plate, fig. 8, is situated. The spring plate e, fig. 8, carries a spring which rotates the locking handle G. This spring plate is held in place by the lugs f taking into the recesses g formed on the rear of the end-piece, fig. 3. H, fig. 1, is the handle cover plate which screws on to the extreme rear of the end-piece, fig. 3, and which is checkered on its upper face to facilitate the carrying and manipulation of the arm. Separate views of this part are shown at fig. 9. The handle plate is prevented from coming unscrewed by a small check pin, h. The main spring i, fig. 1, projects through the breech shoe B, and works in the slot j of the breech bolt (see fig. 2). The trigger k is jointed to the under side of the shoe cap, the toe of the trigger engaging with the underside of the spring i. I is the trigger stop lever, which is firmly jointed also to the shoe cap. The bent end of the lever, while in action, rests against the trigger shank, and prevents its movement. The rear end of the trigger stop lever is held down by the locking handle so long as the breech bolt remains unlocked, but when securely locked, the handle G, fig. 1, is partially rotated until the slot m, fig. 7, coincides with the rear of the stop lever, when the trigger k and the stop lever are free to move, and the gun may be discharged. n, fig. 1, is the trigger lock jointed to the guard, and is shown separately at fig. 10. The lock is shown open, but when the gun is loaded, and it is required to carry it so, the lock or plate is turned down against the trigger shank k, and, while in this position, the trigger itself is immovable, and consequently the discharge of the gun is rendered impos-

The gun is manipulated as follows:-The locking handle G is first gripped with the thumb and forefingers, and turned to the right, the plug D being withdrawn at the same time from the breech chamber. The cartridge is next dropped into the opening in the breech shoe, and the bolt pushed home with the hand, when the rifle is ready for firing. After firing, and on withdrawing the breech bolt for reloading, the cartridge case is extracted by the extractor hook o, fig. 1, which is attached to and carried by the breech bolt. This hook, on closing the breech, engages with the base plate of the cartridge, which, on being withdrawn by the extractor, is caught by a small tilting pin p in the bottom of the breech shoe, and is tilted from the chamber. It will thus be seen that two movements only are required in this arm for opening the chamber-extracting the empty case, and completely closing the gun for firing, which obviously renders the action the most simple and rapid hitherto produced, the movements, in fact, being reduced to the

ments of the inventor. The fifth was a well-finished pattern of the carbine, recently supplied by the proprietors, Thomas Wilson and Co., of 15, Cockspur-street, Charing-cross, to the French Government, and had the same bore and rifling as the Chassepot pattern. The ammunition was on the Boxer principle, with a bullet of pure lead weighing 400 grains, and having a solid flat base. powder charge was 75 grains, and the lubricating material pure beeswax. The trials commenced by firing ten rounds from each rifle, which was very rapidly accomplished, and the arms were afterwards minutely examined by those present; each gun was then fired for range and accuracy at 200 and 500 yards, and some very good practice was made at both ranges. At the latter, Captain O'Hea made five bull's eyes and eight centres in twenty rounds, not withstanding the wind was very strong and gusty, and blew across the range. One of the rifles was then fired by Mr. Wilson for rapidity and fouling, 100 rounds being discharged very rapidly and without intermission from one barrel, without watering or cooling. On examining the rifle after this test, the barrel, which was very hot, exhibited little or no sign of fouling, the breech mechanism was perfectly clean and cool, and the action worked as freely and smoothly as at the commencement of the trial. The extractors worked perfectly, and withdrew and tripped every cartridge case from the chamber with the greatest ease and certainty; in fact, nothing could exceed the smoothness and rapidity with which all the actions worked. One gentleman fired 12 rounds in twenty-eight seconds, shouldering the gun at each round. About 500 rounds were fired in all, and the trials gave general and marked satisfaction.

It is but fair to state that a number of missfires took place during the trial, but it was found on examination that they occurred only with the Woolwich-made cartridges, and that not a single miss took place with those made by Messrs. Eley Brothers—a fact much commented upon by those present. About 200 of the Woolwich-made cartridges were used at the trial, the rest having been supplied by Messrs. Eley Brothers, of the Gray's Inn-road. On dissecting several of the cartridges which missed fire, it was found that one was without an anvil, and another without any powder; the bullet cap and anvil in this cartridge were perfect, but having no powder the bullet remained undischarged; the cap, however, had been exploded. Failure in this respect could not of course detract from the merits of this arm, which, during Friday's experiments, proved itself to be—as far as those experiments went—a most efficient weapon, compact and simple in its arrangement, handy and effective in action.

# MANUFACTURE OF CAPS AND CARTRIDGES.

No. II.

ONCE determined upon putting into execution the design of establishing a manufactory, where the employment of fulminating ingredients would play a prominent part, M. Gevelot lost no time in carrying out the scheme. His first step was to purchase the stock-in-trade of many former manufacturers of those dangerous compounds, which many of them parted with, on comparatively easy terms, as they were heartily tired of their perilous business. Without being cast down by the difficulties in his path, nor by the frequent acts of treachery committed against him by some of his employés, who betrayed his secrets to his rivals lowest possible minimum.

There were five rifles used upon the occasion of the trial; four were of the new English pattern, 4in. shorter than the Enfield rifle, -450 bore, rifled in 6 grooves, with 1 turn in 25in., and embodied all the recent improve-

present time, owing to the care employed in the construction of the various buildings, and the manner in which the work is organized, no accident of a serious character has taken place. This is the more to be wondered at, as, in consequence of the enormous duties levied by the revenue authorities upon gun-powder, many manufacturers are in the habit of mixing a proportion of fulminating ingredients with the powder, the effects of which cannot be accurately estimated. Towards the close of 1836, the manufacture of cartridges for breech-loading sporting guns was commenced. It is generally considered the principle of loading guns and cannons by the breech, instead of by the muzzle, is quite a modern invention, but such is not the case. The first cannons were charged in this manner, and under the Renaissance, some were made upon that principle. But all these arms, from the "Amusette" of Marshal Saxe, to the guns with movable breeches which immediately preceded those of Lefancheux, were attended with too many practical defects and inconveniences, ever to gain universal favour. It is true, that the carbine of Lepage was tried in several cavalry regiments, but only for a brief period, as it ultimately failed to prove satisfactory. It must be kept in view, that it is not sufficient to obtain merely a happy combination of the different parts that compose a gun. Its successful working, and the facilities it will afford for rapid loading and firing, depend quite as much upon a multitude of conditions that must be fulfilled by the cartridge. Notwithstanding all that has been achieved, and even attempted, in this line, there is still abundance of room for further improvements. In describing in detail the manufacture of

cartridges, there are several particulars which will be treated of most effectually and succinctly by being introduced seriatim. is, first, the copper envelope or case; secondly, the fulminating compound itself; thirdly, the preparation of the felt; fourthly, the making up of the cases; and, fifthly, the filling or charging of them. All of these progressive operations will be fully described, and we will commence with the caps. They are formed of the purest red copper, chemically represented by the formula Cu 2 O, which must be possessed of an extreme degree of malleability. It is received at the establishment in the shape of long strips, which are thicker than are needed for the finished envelope. These strips are cut into short lengths, and passed through a succession of small rollers which reduce them to the required thickness. Everyone is familiar with the thickness of an ordinary percussion cap, and is aware that it slightly exceeds that of rather stout tinsel. After passing through the rolls, the short strips of copper are rendered case hardened, and so brittle that it would be impossible to use them in that condition. To restore to them the necessary degree of temper, they are rolled up, placed in a furnace, and annealed at a red heat. By these means, the ductility and malleability of the material is restored, but at the same time the colour is changed to a most disagreeable shade of dirty brown. The peculiar rosy tint of fresh copper is again imparted to it by plunging it into water strongly acidu-lated with sulphuric acid So 3, washing it after-wards in pure water, and finally beating it with woollen beaters in a quantity of sawdust. So soon as the surface has regained its proper colour, and become perfectly clean, the little fillets or rolls are submitted to the action of stamping machines, some of which act vertically and some horizontally, but all accomplishing the same result, with that identity and precision so strongly characteristic of the agency and operations of

the cap is caught by a small projecting arm. During the operation, small fragments are detached, which will be alluded to again in a future part of our articles. There are various descriptions of caps, some of which are smooth, and are cut and stamped out of a single piece of metal. This quality, which is also sometimes manufactured from yellow copper, Cu. O, serves for the priming of cartridges intended for sport as well as war, and also for that of the small cartridges of the "Flobert" gun. The whole category of caps embraces ten varieties. The first is that already mentioned, stamped out of a single piece of copper; the second is grooved upon the lower half; while the third is also grooved, but is, in addition, rendered waterproof by the placing of a small cover of tin over the fulminating powder. Under the fourth head, we have the ring cap, or that furnished with a large ring, to prevent all The fifth has an chance of explosion. hexagonal shape, with small facets upon it, which renders it easily manipulated. sixth variety, the rim is flattened out; and, in the seventh, the fulminating compound is placed at the other end. There is a notable difference in the eighth, which is of inferior quality, and manufactured of brass. As a contrast to its predecessor, the following is of the best quality, made from red copper, while the tenth and last constitutes the small specimens used in children's pistols and other warlike toys of a similar character.

Those caps that are intended for the old description of sporting gun, of which there are more in existence than is generally supposed, are prepared in such a manner as to obviate the possibility of driving a piece of the copper into the eye of the firer, an occurrence which is very likely to take place with the caps made all in one piece. The machine which cuts out the body or envelope of the cap, cuts it into four or six pieces, according to the type that is chosen. Thus, for the grooved cap, the copper is cut into four pieces or wings; into six, for the hexagonally shaped, or fifth variety; and into a similar number for the next in the above category, only that the wings are somewhat longer, in order to allow of their being turned up at right angles after the stamping has been When the copper is cut into this finished. shape, the punch descends upon it, and forces the fragments altogether towards the centre This joining is effected so completely that no seams can be seen until the cap has been exploded, which causes them to reopen. These latter descriptions of caps are grooved upon both faces, and marked with a G. which is the trade mark of the establishment, at the same time that they are stamped. The machines executing this work can turn out 130,000 caps in a day, and as they number, in all, ten, about a million and a-half can be manufactured, on a push, per diem. Previous to the operation of stamping, a small sponge, full of colza oil, is passed over the strip of copper, so that the caps, when first coming from the machine, are in a greasy condition. They are cleaned and dried by placing them in a barrel filled with sawdust, to which is imparted a movement of rapid rotation. This preliminary operation is sufficient to remove all grease from the caps, but does not bestow upon them that vivid tint they present to the eye when a boxful is opened for the first time. All that is necessary to impart to them this appearance is to subject them to a certain amount of friction. For this purpose, a large number of them are enclosed in an apparatus consisting of four sacks, stretched between the extremity of the four arms of a cross, which is caused to revolve. At each turn they are thrown, as it were, from one arm of the cross to the other, and, by the friction, not only obtain a brilliant polish, but become shorn of any little roughness and asperities that

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

A NEW PHOTOMETRICAL ARRANGEMENT-THE USE OF PETROLEUM IN PLACE OF BISULPHIDE OF CARBON IN THE VULCANIZATION OF INDIA-RUBBER -HYDROGENIUM.

AVING had occasion once or twice to refer to the imperfections of our methods of determining the relative luminosity of a gas flame, we may briefly refer to a new photometrical arrangement, devised by Mr. Crookes, which seems to possess some advantages over those in common use. The defects in these are of two kinds-one in the instrument itself, and the other in the standard of comparison. For the latter, sperm candles are now most commonly used, that is, candles o spermaceti, with just sufficient wax (about 2 per cent.) to prevent crystallization. Owing to various circumstances, which would occupy us too long to enter upon here, these candles burn with great irregularity. According to Act of Parliament, they should each burn at the rate of 120 grains per hour, and the Gas Referees have recently ordered that all experiments shall be rejected in which they have burned more than five grains above or below the standard. In fact, however, it is rare now to find candles which will burn within five grains above the standard. The fault, no doubt, lies chiefly in the wick, for spermaceti is a body of uniform composition, and the manufacturers of candles for gas testing have no temptation to adul terate it. The oil lamp of the Moderator or Carcel pattern, which is used in Paris, and recommended by some for adoption here, is open to most of the objections which apply to candles. To ensure anything like uniformity of combustion, nice attention has to be made to the manufacture of the wick, to the construction of the lamp, and to the regulation of the height of the wick while burning. A greater difficulty, porhaps, is to obtain oil of perfectly uniform character. In Mr. Crookes's plan, all difficulties, as regards the wick, and the composition of the burning material, are avoided. wick is a bundle of platinum wires of very small dimensions, and the combustible is a mixture of benzol and absolute alcohol. The recommendations of this lamp are obvious. Both benzol and alcohol are definite bodies, always obtainable in a perfectly pure state, and the wick being uniform and incomonly vary slightly with the temperature. The objection is that the standard of comparison will not be popularly understood. The public understand what is meant, when it is said that it will require fourteen candles to give a light equal that of a certain gas flame. But when it is said that a gas flame gives a light equal to that produced by the consumption of so many grains of benzol and alcohol, it does not convey a very clear idea to the public mind. This objection, however, is popular not scientific. The means of determining the point of equal luminosity also differs from that commonly employed. Instead of having to observe the equal illumination of a spot as in a common Bunsen's photometer, the experimenter has to observe two discs of different colours, which as the feebler light approaches the stronger become equal in tint—the point of equal illumination. By all experimenters not affected with colour-blindness, this point may no doubt be hit "with great precision"—with greater precision than by the use of the paper discs with the translucent spot, which, reason or other, vary greatly in sensitive-We have said enough to call attention to this instrument, which, now that the whole subject of gas examination is under revision, and pending the discovery of the means of making an absolute measurement of light, seems to us to merit a fair consideration.

The use of a mixture of bisulphide of carbon and chloride of sulphur for the superficial vulcanization of india-rubber, is open to some objections. In the first place, the vapour of bisulphide of carbon is exceedingly noxious to health, and its great volatility and the low igniting point of the vapour

petroleum in place of the bisulphide. For this purpose the petroleum must be completely deprived of water. This is done by first treating it with strong sulphuric acid and then after decantation rectifying it by distillation from caustic potash and a little oxide of manganese. Bisulphide of carbon is very cheap, but probably the rectified petroleum could be produced cheaper. In a sanitary point of view, however, it deserves consideration, independent of cost. One objection to the substitution may perhaps be found in the fact that petroleum is a much worse solvent for india-rubber than bisulphide, and the sulphur might not penetrate the rubber so well.

A few additional notes may be made to our short account of Mr. Graham's researches on the nature of hydrogen. This he regards as the vapour of a metal which he proposes to call Hydrogenium. In palladium, fully charged with hydrogen, he considers that there exists a compound of palladium and hydrogenium in equal equivalents. As regards bulk, he has established that the alloy must contain twenty volumes of palladium to one volume of hydrogenium. He considers that the latter metal possesses a certain amount of tenacity, and also electric conductivity, like other metals, and also that it must be classed among magnetic metals. Some consequences of Mr. Graham's discovery were pointed out by M. Dumas. "Water," he said. "must be recorded as the collection." must be regarded as the oxide of a metal.' Mr. Graham, however, has said that he has satisfactory evidence that oxygen, too, is a metal; hence we must look upon water as a metallic alloy. All the so-called organic bodies, M. Dumas also remarked, must be supposed to have a metallic basis. One other fact remains to be mentioned; the hydrogen at the moment of its liberation from the alloy in the gaseous form, is an excedingly active reducing agent, which seems conclusive as to the reality of the combination of two metals. Nascent hydroven, we all know, bears the same relation to ordinary hydrogen that ozone bears to ordinary oxygen, and in both cases we may suppose the superior activity to be a consequence of the condensation.

### INSTITUTION OF MECHANICAL ENGINEEERS.

THE twenty-second anniversary meeting of the members of this Institution was held on Thursday, January 28, in the Lecture Theatre of the Midland Institute, Birmingham; John

Penn, Esq., President, in the chair.

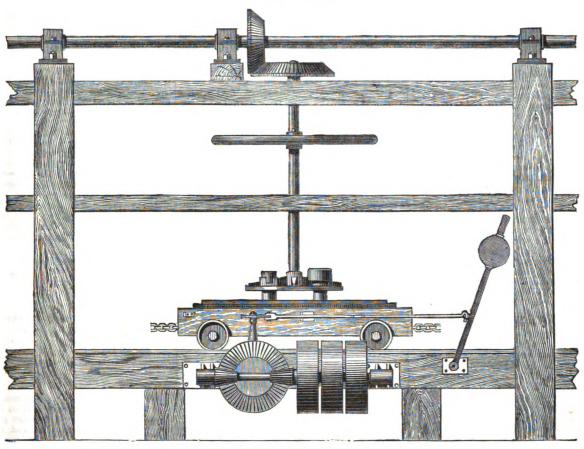

The Secretary (Mr. W. P. Marshall) having read the minutes of the previous meeting, the annual report of the Council was then presented, which wood the very satisfactory progress of the Institution during the past year, and its prosperous condition; and reference was made to the large and important meeting of the Institution held in Leeds last summer. The annual election of officers then took place. Sir William G. Armstrong being elected President of the Institution for the present year, the meeting of the Institution in the ensuing summer being intended to be held at Newcastle-Several new members were upon-Tyno. elected

A supplementary paper, by Mr. Charles Cochrane, of Dudley, was read, in continuation of the paper read at the previous meeting, "On the Further Utilization of the Waste Gas from Blast Furnaces, and the Economy of Coke due to Increased Capacity of Furnace." Taking the maximum limit to the size of a blast furnace to be that at which the temperature of the waste gas evolved from the furnace top will have become cooled down to the temperature of the external atmosphere, by its passage upwards through the materials contained in the upper part of the furnace, it was pointed out that in the Cleveland district this limit of size would be reached sooner than was represented in the previous paper, because in the calculation there given, a correction is required for the reduction in the consumption of fuel per ton of iron made in furnaces of increased capacity. reduction in consumption of fuel causes at the same time a corresponding reduction in the quantity of gas evolved per ton of iron made; and consequently, by reducing the proportionate quantity of gas to be cooled, will cause the actual reduction in temperature of the escaping gas to be greater than was obtained by the calculation given in the previous paper, so that the maximum size of furnace will be sooner arrived at. Without taking into account the effect of the increasing difficulty ex perienced in establishing an equilibrium of temmight have existed on their surface. In our is a constant source of danger from fire. Under perature between two bodies when they more next, we shall proceed to describe the manu-these circumstances, it has been proposed to use nearly approach each other in temperature, it was

# PYRENEAN MARBLE POLISHING MACHINE.

BY M. CANTET.

argued that the maximum size of furnace would be reached with a capacity of about 2½ times that of the present large Cleveland furnaces of 20,000 cubic feet capacity, supposing the calcined ironstone to contain 40 per cent. of iron, and the blast to be delivered into the furnace at a temperature of 1,000deg. Fah.; and in such a furnace it was estimated that the consumption of fuel should then be reduced to about 18cwt. of coke per ton of iron made.

The further question was also considered, whether a variation in the rate of driving of a blast furnace materially affects the economy of fuel; and the results were given of the actual working of two furnaces at the Ormesby Iron Works, Middlesbrough, the larger having nearly three times the capacity of the smaller. From this comparison, extending courselves are reviewed of working it was extending over long periods of working, it was shown that the differences in the rate of driving, though considerable in amount, did not sensibly affect the economy of fuel; leading to the con-clusion that an increased rate of driving of a furnace does not produce any unfavourable effect on the temperature of the escaping gas, but, on the contrary, is slightly favourable to economy of coke, within certain limits of variation in the rate of driving, according to each particular size of blast furnace

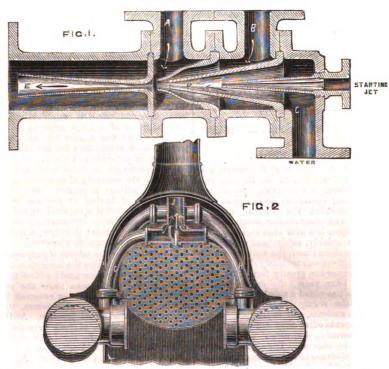

After the meeting, a number of the members and their friends dined together, in celebration of the twenty-second anniversary of the Institution.

## MARBLE POLISHING MACHINE.

A VERY large proportion of the marble used in France for building and decorative purposes is derived from Pyrenean sources, and of these the head quarters are at Bagnères de Bigorre. nead quarters are at Bagneres de Bigorre. Our engraving represents a simple machine for polishing marble slabs, invented by M. Cantet, of that place, and used in the works of the firm to which he belongs. In its action it somewhat resembles a belongs. In its action it somewhat resembles a planing machine, inasmuch as the little truck carrying the stone is propelled automatically backwards and forwards along its bed, and reversed as the polishers reach the ends of the slab. As the machines are used at present, several of them are ranged in line with the carriages connected by chains working round a drum under the frame, and attached to the bevel wheel shown in our cut. The action of this drum is reversed in the usual

#### THE EJECTOR CONDENSER.

MR. MORTON.

way by the lever balance weight and the three drums. Two projecting catches fixed to the truck impart the necessary movement for starting the reversing gear at the required moment. The marble to be polished is attached to the truck by a bed of plaster of Paris, and is acted upon by lumps of sandstone carried in the revolving wheel immediately above the stone. These pieces of sandstone are dropped into ferrules carried in the wheels stone are dropped into ferrules carried in the wheels after having been roughly shaped, and are pressed upon the stone by heavy cast-iron caps resting on the top of the polishing stones, so that as they wear they are still kept in contact with the face of the They measure five metres in height by about sixty-

marble. In the illustration, one of the caps is removed to show the head of the stone. A constant stream of water is kept flowing over the marble surface. After it has been sufficiently ground, it is finished by polishing with colcothar. The works of Messrs. Cantet Frères have been six years in operation. The amount of marble worked per week in their ateliers amounts to upwards of seven cubic metres, all of which is excavated from their quarries, about four miles to the south of the town. Eight of the large polished marble columns for the Grand two centimetres in diameter, and weigh 4,000 kilogrammes each. They were each turned out of a solid block, in a huge lathe specially constructed for the purpose, and, we understand, cost £200 each delivered at their destination.

### MORTON'S EJECTOR CONDENSER.

T the thirty-first annual meeting of the Liver A pool Polytechnic Society, held November 21, 1868, the president, Mr. J. T. King, read an address, in the course of which he referred to the progress of mechanical engineering. Under this head occurs the following description of Mr. Morton's ejector condenser. In mechanical engineering, Mr. Alexander Morton, of Glasgow, has devised and successfully carried into use most valuable improvements in connection with the steam engine. A correct appreciation of the merits of induced or what are known as lateral induction currents of fluids by jets, has enabled Mr. Morton to give to the world means whereby the benefit of a partial vacuum on the exhaust sides of the pistons in locomotive engines can be secured without working parts, and the benefit of a perfect or almost perfect vacuum in other engines where a supply of water is available, without the employment of an air-pump and also without working parts. In the engraving, fig. 1 is a longitudinal section of that modification of the new apparatus used by Mr. Morton on a pair of engines with inverted cylinders, and by which a of engines with inverted cylinders, and by which a steady vacuum of over 12lb, was maintained. A and B are the exhaust passages; C water supply passage; D central nozzle; E induction tube. When the engines are at work, the exhaust steam is condensed by the water to which it gives motion through C and D, and the speed given to the water escaping through E, maintains the vacuum. F is a steam nozzle for blowing through; where a head of water is available, this can be dispensed with. Fig. 2 shows sufficient of the invention to illustrate its application to a locomotive with outside cylinders. G and H are the exhaust pipes; these terminate in nozzles I and J, the one encircling the other. The exhaust steam from one cylinder produces a partial vacuum in the exhaust passage, and on the back of the piston in the other cylinder.

An invention of this kind needs no recommenda-

tion. It commends itself the instant it is mentioned. If in practice it is only as economical as the air pump, the dispensing with that alone is of the greatest importance; but that it does more, has been certified on the high authority of Professor Macquorn Rankine, whose experiments will no doubt shortly be made public. Coming as it does doubt shortly be made public. Coming as it does within a few months of one hundred years after James Watt's grand conception of the separate condenser, it is an indication to engineers that economy is to be effected where least expected.

## EXPLOSIVE COMPOUNDS FOR ENGINEER-ING PURPOSES.

By Mr. Perry F. Nursey.

A T a meeting of the Society of Engineers, held February 1, 1869, Mr. F. W. Bryant, president, in the chair, the following paper was read:—Engineering operations have from the earliest period included the removal of large masses of rock and other similar natural formations, and the object has ever been to effect their displacement as quickly, safely, and cheaply as possible. In the olden times, the work of removing these obstructives was tediously slow, but the invention of gunpowder greatly facilitated such operations. In later years, the development of chemical science has added a number of explosive compounds to the scanty list of those at the command of the ancients, and in the present day we have many agents other than gunpowder, and much more powerful, by which blasting and quarrying may be effected. The objects in view in producing a substance to supersede gunpowder, are—or, at any rate, should be—to obtain a material which shall possess a more violently explosive action; which shall either cost less, or what is the same thing do an access or greater. what is the same thing, do an equal or greater amount of work with a lesser quantity, and, above all, which shall be non-explosive except under the actual conditions of work. This latter quality is, perhaps, the most important, and has been rendered so by the innumerable accidents which have happened with gunpowder either when in store or at the time of use. The purpose of the present paper is to notice what has been done towards superseding gunpowder, and to indicate the substances which practical experience points

out as being the best to take its place in engineer

ing operations requiring its aid.

Although many attempts have been made to supersede gunpowder, but few have practically succeeded, and this arises not so much from any inadequacy on the part of the substitutes, as egards power, but on account of the extreme liability of most of them to premature explosion from varying causes. Gunpowder itself is open to this objection, and hence the propositions to reduce the risk by mixing it with protecting ingredients. But this is not enough: we must go a step further. What is required is a material over which we can have perfect command, one which shall do no more than burn when in contact with air, but which shall equal, if not exceed, gunpowder in its power when ignited in an air-tight chamber, as in a bore-hole, or the barrel of The necessity for this is evidenced almost daily in one or other of our mining districts, where a large percentage of the explosions occur in the blasting operations. How frequently is gunpowder ignited by stray sparks, even when standing about, but much more frequently do accidents arise when tamping is going on. Here the contact of the metal rod with the rock leads to many a fearful accident. So much is this so, that the Royal Cornwall Polytechnic Society have taken the matter up, and have suggested safe methods of performing this dangerous operation. But however areful a miner may be, there never can be perfect immunity whilst he has to deal with a material which carries within itself all the elements of danger and destruction. To meet the case, a perfectly inexplosive material is required, one which will not explode so long as the atmosphere has access to it, but in which all the active energy of gunpowder is developed immediately it is fired out of contact with the air.

Gunpowder itself is at present more largely used than any other explosive material, and it is a remarkable fact that notwithstanding the centuries which have elapsed since its first discovery, no radical or permanent change has been effected in its composition. Slight variations, it is true, have been made from time to time in the proportion of its constituents, but, in the main, gunpowder remains much as it was 600 years ago. But the danger ever present in handling this material has always been so patent that many years since means were devised for rendering it harmless while in use. Colonel Ryley was the first to propound this theory, and he submitted his plans for enveloping the grains of gunpowder in bone dust, to the Government some twenty-five years since. In later times-in fact, very recently-Mr. Gale's proposition to render gunpowder non-explosive and explosive at will has been much before the His plan was to mix ground glass with the powder for storage and transport, and to sift it from it again when it was required for use This addition of a large amount of a foreign substance with the powder no doubt answers the purpose most effectually; but unfortunately there are practical difficulties in the way of its adoption. The objections are, increased bulk and weight for transport, the necessity of numerous sets of mixing and sifting apparatus, and the utter impropriety of having to prepare an explosive material just when it is required for use. Besides, in blasting operations, the accidents usually occur in charging the mine; therefore, a system of this kind would be of no value whatever.

Before quitting the subject of gunpowder, it may be interesting to notice the force this material is capable of exerting when used for blasting purposes. The following particulars show the amount of earth or rock thrown down or removed by 1lb. of powder under various circumstances, the results being taken from actual practice. At the Round Cliff, Dover, 85,232lb. of chalk were thrown down by 1lb. of powder. In the Leith cutting, Tun-bridge, 31,860lb. of hard white sand were moved by the same weight of powder. At Plymouth 22,000lb. of limestone were moved per lb.; in small charges only 8,900lb. were moved. In Antrim, 45,084lb. of white limestone, and 32,430lb. of winstone or basalt were moved by 1lb. of powder. At East Dunmore, 14,280lb. of hard conglomerate were moved; and on the Londonderry and Colembia 23,400lb. raine Railway, 22,400lb. were thrown down by 1lb. of powder. Taking the mean of these results, we have 32,832lb. of material to 1lb. of powder.

Numerous compounds have been brought forward from time to time, for which it has been claimed that they perfectly superseded gunpowder. But, until very recently, no material has been found

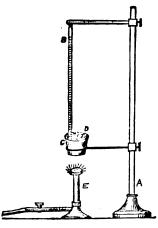

fulfil perfectly all the conditions and requirements of that most important material. Saltpetre is the agent to which the characteristics of gunpowder, as an explosive material of permanent character, are mainly due. It is to the substitution of other nitrates for this constituent that most attention has been given, and the nitrates of sodium, lead, and barium have been successively tried. But although the products, which have been known by the names of soda-gunpowder, and barytic-powder, &c., have obtained a certain amount of temporary success, they have ultimately been abandoned. In fact, all mixtures of this class, when compared with gunpowder proper, have been found to exhibit important and radical defects. Chlorate of potash has been a favourite substance with inventors, notwithstanding its violently explosive nature. The object has, of course, been to tone down its violence by proper admixture with other ingredients, and the resulting products have been to some extent successful. One of the earliest mixtures of this class was German or white gunpowder, which was tried, but proved unauccessful. Many preparations of a similar character have also been brought before the public. Of this class is Ehrhardt's powder, the invention of which is also claimed by Mr. Horsley. M. Ehrhardt's compositions are as follow :-

• •							
BLASTIN	iG :	Po	WD	KR

Mr. Horsley's powder is a compound of chlorate of potash and gall nuts in proportion by weight of three to one. The ingredients are ground sepa-rately to a state of fine powder, and then passed, also separately, through a very fine wire sieve. The two ingredients so prepared and thoroughly dried are blended when required to form the explosive compound. The blending of the ingredients is safely and easily accomplished by passing them in a mixed state through a series of horsehair sieves arranged one below the other, and set in motion. Upon the upper sieve the two ingredients are first mixed by being run together from two receptacles placed above the sieve, one containing a given weight of chlorate of potassa, and the other one-third of such weight of gall nuts. As the chlorate of potash is much heavier than the gall nuts, the volumes or measures of the two receptacles are about equal. Motion being imparted to the sieves, and as the two finely ground ingredients pass downwards through the sieves, they become blended, and form the explosive compound. Powders in which chlorate of potash is an ingredient are undoubtedly somewhat dangerous. The fact, however, of cannon priming tubes, which are composed of chlorate of potash and ter-sulphide of antimony, having been prepared, stored, and used for more than thirty years past without accident, ought to relieve apprehension on that score. ought to relieve apprehension on that score. When treated, as it should be, with care, and not improperly blended with combustibles, chlorate of potash is practically safe. With regard to the explosive powers of Horsley's powder, it may here be interesting to adduce a few facts in the shape of results of trials which came under the author's notice, and which were made to institute a comparison of its strength as against gunpowder. eprouvette, weighing with its carriage 10lb. 20z., was placed on a fir plank in a perfectly level position. The charge in each instance consisted of position. The charge in each instance consisted of 50 grains of the various powders, and was kept in place by a small wad of thin paper. The recoil of the eprouvette, when charged with fine grain sporting powder, was 9-16in.; with very fine grain sporting powder, 11-16in. Fine grain sporting powder in a state of meal, and compressed by a weight of 400lb, on the square inch, gave a recoil of 42-16in. Horsley's powder in a similar state of meal, and with a similar pressure of 400lb, per square inch, showed a recoil of no less than 119-16in. These results afford some idea of the relative power of Horsley's powder and the best gunpowder. power of Horsley's powder and the best gunpowder. The author has examined some blocks of elm which had been submitted to experiment to show the comparative disruptive force of Horsley's that they perfectly superseded gunpowder. But, powder and of common gunpowder. In each until very recently, no material has been found case equal charges were used, and the eprouwhich would answer all the practical purposes, and vette was discharged one inch from the wood

and at right angles to its face. The disruptive force of Horsley's powder on the wood was as if a solid body had been driven into it, separating the fibres and tearing a hole completely into it. The force of the small grain best sporting powder merely left a mark upon the surface of the blocks.

And here the author would slightly digress to say a few words upon the ignition point of explosives. Although the temperature at which explosive compounds will ignite is an important element in the investigation of their character, the author is not aware that any but the rudest means have hitherto been adopted to ascertain their ignition point. In one instance which has come under his notice, these means consist simply in placing the powder to be tried in one of a pair gun barrels, a thermometer being inserted in the other. On the application of the required heat, the powder ignited, and the temperature was registered by the thermometer in the other barrel. But this plan is open to objection on account of several defects, which will be apparent from the comparatively rude nature of the test. defects, however, are entirely absent from the apparatus shown in the annexed woodcut, and thich was devised by Mr. Horsley, for ascertaining the ignition point of explosives. This it does with the greatest exactness in all cases, giving the most satisfactory results. It consists of a stand A,

from which is suspended by the upper arm a thermometer which is graduated to 650deg. This thermometer dips into the oil bath C which is held by the lower arm. D is a small cup which floats in the oil, and in which the explosive is placed. The oil is heated by the flame from the gas jet E, which is furnished with a stop-cock for regulating the tlame. As soon as the temperature of the oil reaches the ignition point of the powder, the latter explodes, the exact degree being correctly registered By this apparatus, Mr. the thermometer. Horsley has ascertained the ignition point of various explosives, and the following are among some of his results: - Gunpowder ignites at a temperature of 600deg. Fah. A sample of Mr. Horsley's powder gave 430deg, as the ignition point. Guncotton of a powerful character, prepared by Mr. Horsley, ignited at 325deg., whilst some of Prentice's sporting gun-cotton exploded at 410deg. Trials of Schultze's sporting powder gave 385deg, as the ignition point. It is as well, at a time like the present, when new explosive compounds are constantly being brought under notice, that experimenters should know the character of the material they are dealing with, and which they will be enabled to ascertain by means of the above simple apparatus.

Another, and perhaps safer, application of chlorate of potash to the purpose in question was made some nine years since by M. Hochstädter, a German chemist. Unsized paper was thoroughly soaked in, and coated with, a thin paste consisting of chlorate of potash, finely-divided charcoal, a small quantity of sulphide of antimony, and a little starch, gum, or some similar binding material, water being used as the solvent and mixing agent. The paper was rolled up very compactly and dried in that form. In this manner, very firm rolls of an explosive material are obtained, which burns with considerable violence in open air, and the propelling effect of which, in small arms, has occasionally been found greater than that of a corresponding charge of rifle powder. Moreover, the material, if submitted in small portions to violent percussion, exhibits but little tendency to detonation. But as no reliance can be placed on a sufficient uniformity no reliance can be placed on a sufficient uniformity of action, in a firearm, of these explosive rolls, this alone sufficed to prevent their competing explosive power. Here, then, is a powder, which

with gunpowder. The same description of explo sive preparation, differing only from that of M. Hochstädter in a tritling modification of its composition, was again brought before the public in this country in the early part of 1866, having been patented by M. Reichen. The author has used this patented by M. Reichen. The author has used this gun-paper with very good results in rifle shooting but nothing practical appears to have been done with the material.

The mixture previously referred to as German or white gunpowder consists of chlorate of potash, ferrocyanide of potassium, and sugar. Many years since, it was proposed and tried without success as a substitute for gunpowder. Since then various preparations of similar character have been suggested for employment, either as blasting and mining agents, or for use in shells, or even for all the purposes to which gunpowder is applied, The most recent of these mixtures, with which the author is acquainted, is a white gunpowder made by Mr. H. W. Reveley, of Reading. This mixture is a perfectly white impalpable powder resembling flour, powdered chalk, or magnesia in appearance. Mr. Reveley recently informed the author that he has constantly made and used it in preference to the ordinary gunpowder, both on account of its superior propelling power-which is at least one-third greater-and its perfect clean-It produces neither smoke nor flash of flame at the muzzle on discharge, and can be used in a casemate with perfect comfort to the gunners Mr. Reveley has used it for every purpose to which ordinary gunpowder is applicable, and invariably with the most perfect success. He has made many parcels of the white gunpowder during the last ten years, and has always found them uniform both as regards strength and other properties, and he has never met with the slightest accident. although he has tested it very severely. The composition of white gunpowder is as follows:-

> Chlorate of potash Chlorate of potash . . . 48
> Yellow prussiate ditto . . . 29 Finest loaf sugar

> > Parts by weight .

In manufacturing this powder the yellow prussiate is dried in an iron ladle until it is as white as the chlorate. The ingredients are ground separately to very fine powder, and are then mixed by means of a conical sieve until they are thoroughly incorporated, but not by trituration. For small quantities, Mr. Reveley uses a common Wedgewood mortar and pestle, which must be perfectly dry and The operation does not take many minutes, and with the above precautions, its manufacture is free from danger. In loading, it is treated in the same way as ordinary gunpowder, being pressed down by hand solid, but not hard. The charge is down by hand solid, but not hard. ignited in the usual way, with a common cap and In actual use, it does not appear to possess a bursting so much as a propulsive power, and Mr. Reveley has obtained some of the highest penetrative results in his rifle practice with it. economy of this powder will at once be apparent, when it is stated, that its wholesale cost is about 86s, per cwt., but as its strength is at least onethird greater than that of ordinary powder, its cost may be comparatively estimated at about 60s. per One important feature in the manufacture of white gunpowder is that it does not require to be -indeed, it cannot be-granulated, which process is the great source of danger in powder-mills. The universal use of the cartridge entirely obviates any objection that may be made to white gunpowder on that score, or on the score of similarity in appearance to other substances, and, owing to its compact form, it only occupies half the usual space. Besides the foregoing, there have been several cruder applications of chlorate of potash in the production of explosive compounds, which it is unnecessary here to notice more particularly.

Amongst other materials, wood has been pressed into service to the aid in superseding gunpowder as a practical explosive. Soon after Schönbein's discovery of gun-cotton, a Prussian artillery officer, Captain Schultze, whilst investigating the subject conceived that finely divided wood could be con verted into a controllable explosive agent more readily than cotton. He produced the substance known as gun-sawdust, the explosive properties of which are mainly due to its impregnation with a large proportion of an oxidizing agent. In preparing the gun-sawdust, the wood is purified from all resinons substances, and is digested in a mixture of sulphuric and nitric acids. This gives a very feeble explosive material, which is further

may be preserved in a comparatively harmless condition until required for use, when it may be rendered powerfully explosive by impregnation with the nitrates. Although its properties are somewhat similar to those of gun-cotton, many of the advantages of which it possesses, it is open to one very fatal objection. To be within the limits of safety, completion of its manufacture must be delayed until the moment it is required for use: and, moreover, the final ingredients are the most dangerous, and require refined manipulation. It is needless to point out how incompatible the conducting this completing process is with the ordinary details of mining; the care and nicety required in such a chemical operation must be referred to the skilled operator, and not trusted to the rough-and-ready hand of the miner. Practical safety can only be attained by an explosive agent into which the stray spark may fall without producing more than a gush of flame, a gradual burning, or without causing ignition at all, but which, nevertheless, when properly rammed home and tamped, may be fired with results at least equal if not superior to ordinary gunpowder.

During the year 1866, a new kind of blasting powder, which promised to supersede gunpowder in mining operations, was introduced to public notice in England. This was the invention of M. Gustave Adolph Neumeyer, of Taucha, Saxony, and to which the term "inexplosive" may appropriately be applied, inasmuch as there is no possibility of its exploding, either during its manufacture, storage, or manipulation. Not until the proper moment of ignition arrives, when it is well rammed home and prepared to do its work, is its energy developed. Then, and only then, it manifests a power, when used weight for weight, considerably in excess of that possessed by gunpowder. M. Neumeyer, all his life connected with the management of quarries, and himself the possessor of a quarry near Taucha, had his attention forcibly drawn to the distressing accidents, which are of such frequent occurrence in blasting operations, and he conceived the idea of producing a blasting powder which should combine the desired degree of strength, with perfect safety when in work. After a long series of trials and experiments, he succeeded in effecting his object, by the invention of a powder which unites in itself the above important qualities. Within two years from the date of his discovery, M. Neumeyer was manufacturing this powder on a large scale, extensive mills with steam power having been erected for its production in the city of Altenburg, and in two other places in Gormany.

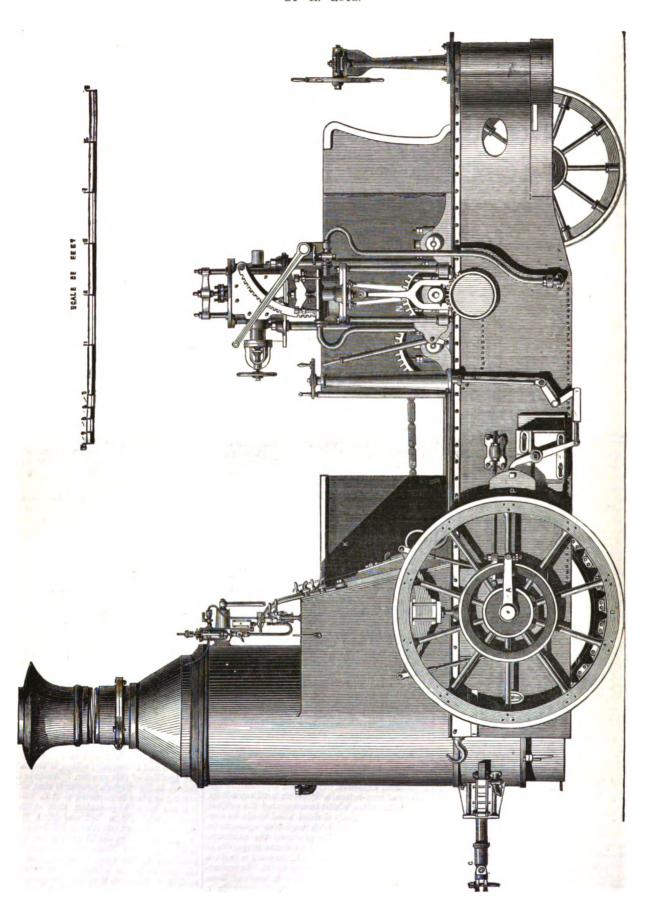

Although Neumeyer's powder differs in colour as well as in action from gunpowder, in that it is slow burning instead of violently explosive when in contact with air, it is composed of precisely the same materials as ordinary gunpowder. To these no other substances are added, the whole secret of the extraordinary result arising simply from the method of proportioning and compounding the ingredients. A reduction is made in the amount of sulphur employed, by which means a much smaller quantity of the noxious vapours is evolved on its ignition than is produced by the combustion of ordinary gunpowder—a point of great importance in underground mining operations. Some difference is made in its preparation, according to the use for which it is required, whether for military or for mining purposes. As a consequence, there results, in the former case, a powder which, when hermetically confined, explodes at the same temperature as ordinary gunpowder, whilst when prepared and charged for blasting purposes, it requires a somewhat higher temperature. so far from being objectionable, is positively advantageous, inasmuch as it makes the possibility of accidental ignition more remote. Bickford's of accidental ignition more remote. Bickford's safety fuse, which is now so extensively used in our own and continental mines, is best adapted for the ignition of this powder. Another important feature in Neumeyer's powder is that, although no Another important coating or glaze is imparted to it in manufacture, it is not more hygrometric than ordinary gunpowder, whilst, if wetted and dried, it is said to retain all its good qualities in full force. Ordinary powder is more powerful as the size of the grain is increased, but Noumeyer's powder, when in a condition of fine dust, is equally if not more efficient than the other. From what has been efficient than the other. From what has been said, it will be seen that the new gunpowder embodies safety in manufacture, in transport, and in handling, preparatory to actual use, whilst it has been proved to be superior to ordinary gunpowder, in point of effective power, so that it may fairly be

BY M. LOTZ.

# TRACTION ENGINE.

FRENCH TRACTION ENGINE.

the accompanying engravings we illustrate a French traction engine, which was turned out from the works of M. Lotz, at Nantes. It is on the vertical cylinder principle, and we are at a loss to understand the maker's reason for reverting to such an inconvenient system. We give the drawings, however, as illustrative of a style which

our foreign maker prefers to adopt, and which he considers perfect. We are unable to furnish our readers with the dimensions of this engine, inasmuch as M. Lotz considers that having spent much time and incurred considerable expense in arriving at what he considers perfection in proportions, he would be a loser by giving to the public information which he values

NEW YORK ASSOCIATION OF ENGINEERS.

IN answer to a circular dated January 12, 1 Nanswer to a circular dated January 12,
1869, about one hundred practical engineers
met on the 15th, at the Howard Mission Hall,
40, New Bowery, New York, for the purpose of
organization. William W. W. Wood, Chief Engineer of the United States Navy-yard, Brooklyn,
was called to the chair, and Mr. G. Weissenborn was called to the chair, and Mr. G. Weissenborn was appointed secretary. After a report was submitted by Mr. George P. Clark, chairman of the committee on organization, Mr. Weissenborn, in response to a request, read an address, in which the importance of union and co-operation was fully detailed. Mr. Hazwell then submitted the collaming reports are applied for experimental which following report as a plan for organization, which was debated, and finally, after some amendments,

The committee appointed at the last meeting of engineers, at the rooms of the Liederkranz Society, in Fourth-street, on the evening of the 9th inst., having considered the matters referred to them, submit the following recommendations

for the consideration of this body:

That the engineers of other States of the Union be invited to form associations, and that, when formed, that they appoint delegates to a general convention of State organizations to represent them in a body to be known as the American Association of Engineers.

That all the subserbers to the prospectus of Mr. L. Weissenborn be neid to be members of this con-

vention.

That the title of this association shall be the New York Association of Engineers. That the officers of this association shall consist

of a president, three vice-presidents, a corresponding and recording secretary, a treasurer and an executive, finance and lecture committee, each of five members.

That the stated meetings of this association

shall be monthly.

That the names of all candidates for membership shall be submitted at a stated meeting, endorsed by ten members, and that they may be voted upon at any subsequent stated meeting. Five black balls or negative ballots shall exclude an applicant from membership.

That the committee on lectures shall report a system of lectures to the president, to be submitted by him to a board of all the officers of the association, and, if approved of by it, said system shall be the rule of proceedings, and that this committee shall then call a meeting of the association

at as early a day as may be practical.

After adopting this for a plan of organization, After adopting this for a plan of organization, and appointing a committee to nominate officers at the next meeting, it was resolved to authorize the chair to appoint a committee on lectures at once. This committee was thereupon named by the chairman, as follows:—Messrs. Raymond, Vanderbilt, Babcock, Holmes, Maine, Germain, and General Burger. Resolutions of thanks to the temporary officers, and especially to Mr. Weissenborn, as the originator of the association, having been passed, a motion to adjourn was adopted, and, by request, the Rev. Dr. Ward, president of the Howard Mission, closed the proceedings with

A NEW AMERICAN BREECH-LOADER.

A NEW breech-loader, the invention of a New Yorker, was recently tried at Springfield Arsenal before a party of gentlemen interested in firearms. A local paper says of the invention:—It introduces a new principle in weapons of this kind, and is said by experts to comprise their excellences and to overcome many of their disadvantages. The essential feature of the new gun is in the mechanism of the lock, which entirely does away with the old-fashioned lock or hammer, and substitutes in its place an ingenious yet simple contrivance which fixes the cartridge and discharges the shell from its chamber with great rapidity and absolute certainty. This "unit lock," as it is called, is in one piece, and has no complicated screws or machinery liable to get out of order or embarrass the operator. There are, besides, other important features, such as a graded raised sight, fitted upon ratchets, which would seem to increase the general efficiency of the arm. This invention was perfected the present year; but it has already been tested by the Prussian, Belgian, and Austrian Governments, and the official reports of these trials speak in high terms of the new breechloader, as do also those at the armoury here who have seen and examined it. The trial was considered generally satisfactory. With the Remington cartridge accurate shots were made at 200, 500, and 700 yards distant, and in quick firing ten shots were discharged in twenty seconds, and twenty shots in fifty-two seconds. The inventor claims that twenty-five shots can be fired in a minute with more, than ordinary accuracy. ordinary accuracy.

(Continued from page 103.)

said to be a safe and efficient substitute for our old powder.

In support of the above assertions, both of its inexplosiveness and explosiveness, the author would observe that he has made some trials, which proved conclusively that Neumeyer's powder possessed both those qualities. But as a greater value attaches to trials made publicly, and the results of which have been placed publicly on record, the author prefers to give these in place of his own limited experience of this powder. First, then, as to its inexplosiveness. This was proved by several experiments made in the grounds of the Crystal Palace in December, 1866. The most con-Crystal Palace in December, 1806. The most conclusive test of this quality of the powder was the following:—A small house, 5ft. square, built of brick and roofed with slate, and having two chimneys made of 5-inch drain pipes, was constructed, and in it 35lb. of Neumeyer's powder, half blacking and half gunnowder were alleged. half blasting and half gunpowder, were placed. On firing this mass an immense body of flame issued through the openings in the roof, but the powder simply burnt, and moved neither brick nor slate. On 3lb. only of ordinary gunpowder being placed in the same structure and ignited, a violent explosion took place, which rendered the building a mere wreck.

With regard to its explosiveness, the author has a number of authenticated reports of numerous and varied trials illustrative of this quality. A few are selected which have been made in mines and quarries in England. The first trials to be noticed were made on the 4th of December, 1866, at the Bardon Hill and the Markfield Granite Quarries, situated near Leicester, and owned by Messrs. Ellis and Everard. The rock at Bardon Hill, which is of a very hard and stubborn character, was rent and cracked in a most satisfactory manner, and a large quantity of material was thrown down, the results being considered highly successful. At the Markfield Quarry one hole was bored horizontally at the foot of an unbroken face of a large extent of solid rock; others were bored vertically. On firing the horizontal hole, the face of the rock was blown out to a considerable extent n every direction, and an unusually large amount of stone was displaced. The vertical shots proved equally successful, and the results generally were highly satisfactory, the quantity of the new powder used being less than that of ordinary powder required for the same amount of work. In a hard, compact rock, too, such as at Bardon Hill, the effect produced by a given quantity of the new powder is much greater than that produced by an equal quantity in a soft or loose rock. It may be as well to mention here that, bulk for bulk, as well to mention here that, bulk for bulk, Neumeyer's powder, when well tamped, is equally as strong, if not stronger, than ordinary powder; whilst weight for weight, Neumeyer's powder is the stronger of the two. In point of weight, the new powder is one-sixth lighter than the old, which, supposing we take them at even prices, gives over 15 per cent. advantage to the former, owing to the fact that bulk for bulk (or one-sixth less weight) gives an equal if not a superior result to the best ordinary powder.

Having seen the successful action of the powder

upon granite, we will now notice its behaviour in slate quarries. On the 11th of Docember, in the same year, five shots were fired at the quarries of the Welsh Slate Company, Rhiwbryfdir, Car-narvonshire. The first shot was in hard rock, the hole being 2ft. 6in. deep, and 14in. in diameter; 21in. of the new powder was used, and was found to do more work than the same bulk of ordinary powder. The second shot was fired in a hole of the same diameter as the last, but 3in. deeper, cut in the same description of rock; the same depth of powder was used, the result being similar to that obtained with the first shot. Shot No. 3 was in a hole 3ft. 6in. deep, by 14in. in diameter, the material bored being pure slate or pillaring rock; the powder filled the hole within 1in., which was occupied by the tamping. The result of this shot occupied by the tamping. The result of this shot was the discovery that the powder was much too powerful—a fault certainly on the right side, and one easily remedied. The next hole was in the same rock as the last, and was 5ft. 8in. deep, with 4ft. 6in. of powder and a light tamping; this exceedingly satisfactory results. In another 14-inch exceedingly satisfactory results. In another 14-inch hole, 4ft. 6in. deep, 2ft. of powder was used, with 2ft. 6in. of hard tamping; the result of this shot was decidedly good, the rock being shattered. On the following day three more experiments were made at the same quarries. With 2ft. 6in. of powder in a 14-inch hole, 3ft. 6in. deep, the shot proved much too strong. The second shot was proved much too strong.

highly satisfactory; but in the third too much power was again developed.

The general result of these experiments is to prove that, bulk for bulk, Neumeyer's powder is much stronger than the powder in ordinary use at these quarries, and which was of the very best description. The question, therefore, arose as to how the strength was to be reduced when pillaring. It was proposed to have paper cartridges of much smaller diameter than the holes, and which would hold only about one-third or one-fourth of the present charge of powder. These cartridges, it was believed, would answer the purpose exceedingly well in the pillaring rock, where it was desirable to cleave the slate without fracture, and would besides produce a very considerable saving of powder.

A few days after the foregoing experiments, a series of trials were made with the new powder at the slate quarries of Messrs. Matthews and Sons, at Festiniog, Merionethshire. Here two holes 2ft. deep, in a hard rock of an underground chamber each half filled with Neumeyer's powder, and two similar holes in a slate rock, were fired with perfectly satisfactory results. Two more shots in the hard rock of the tunnel were not quite so successful; but it was owned that the tamping had been imperfectly rammed, the man having fired them before they were inspected. The two next shots were stated to have done as much with 11in. of Neumeyer's powder as with 15in. of ordinary powder. In another hole in very hard rock of the tunnel, the result was completely successful, it being stated that with ordinary powder two holes would have been necessary, or the shot would not have succeeded in effecting the required detachment. A 14-inch hole, 8ft. deep in hard rock in the open air, was charged with 4ft. 6in. of powder. This shot was considered very successful, for although not much rock fell, an enormous bulk was loosened, which was readily brought down with a small blast of ordinary powder placed in the rent. Experiments have since been made in various collieries to test the capabilities of this powder in the working of coal, and the results have been exceedingly satisfactory, and have fully borne out the expectations formed. Experiments in the copper mines of Cornwall have also given similar results.

The author could give numerous other examples of trials with Neumeyer's powder, which fully sustain its reputation as a blasting material; but enough has been said for the present purpose. He has dwelt at some length upon the merits of this material, because it appears to be the only powder which has proved in every way superior to gun-powder for blasting, and which really embodies comparative safety coupled with greater energy than the ordinary powder. But although so promising in its character, it has not come into practical use in England. An enterprising gentleman, Mr. E. H. Newby, to whom its introduction in our country is due, devoted a considerable amount of time and money in the endeavour to render it a commercial success. In this, however, he appears to have failed, although it is to be hoped such an admirable substitute for gunpowder, that as this material appears to be, may yet find its way into practice. In Germany, the author believes it still continues to be extensively believes it still continues to be extensively manufactured and used.

(To be continued.)

# ON THE CLIMATE OF NORWAY.\*

SEND the first results of my investigations relative to the climate of Southern Norway observations embrace seven years for the stations at Christiansund, Aalesund, Skudesnes, Mandal, and Sandesund; thirty years for the Astronomical Observatory at Christiania; three years for the station at Dovre; and one year for the Meteorological Institute at Christiania. numbers expressing the normal temperature at the different hours of observation for months and stations have been determined. The long series of the Christiania Observatory has enabled me to correct the means of the seven and three years' at the other stations, and thus to render them comparable, as if they were the results of a series of thirty years.

The hourly or two-hourly observations already taken, and which will be continued at certain stations, not yet being completely calculated. I have only been able to determine the daily means

approximately. In this determination I have used the Sa.m. and Sp.m. observations. The daily mean is calculated from the mean of these two quantities, plus a constant. This constant, varying from month to month, has been approximately determined by an interpolation of the values for Christiania and Bergen. The corresponding values for these two places agree with each other in a very satisfactory manner through all the months of the year, and I therefore regard the values of the mean temperature, given below, as very near the truth. As the amount of the corrections to be applied to the mean of 8a.m. and 8p.m. may be interesting to meteorologists, they are given in the following table:-

MEAN DAILY TEMPERATURE =  $\frac{1}{2}(8a.m. + 8p.m.) +$ A Correction. (F.)

	C-	ORRECT	ons.
Fo	r Christiania.		For Bergen.
	Deg.		Deg.
January	+~0.47	•••	+~0.32
February	+ 1.37	•••	+ 0.36
March	+1.55	•••	+0.52
April	+ 0.67		+ 0.25
Мау	-0.36	•••	-0.18
June	- 0.54		— 0·31
July	<b>— 0</b> ·05	•••	+ 0.04
August	+ 0.20		+0.20
September	+ 0.92	•••	+0.32
October	+ 0.86		$\pm 0.29$
November	+ 0.72		+ 0.13
December	+ 0.32	•••	+ 0.13

The effect of the greater diurnal range at Christiania is seen in these numbers. The numbers for Bergen hold good for all the west coast.

The following table contains—first, the monthly temperatures at the different stations; second, the mean annual temperature; third, the periods at which the temperature is equal to the yearly mean; fourth, the maxima and minima, together with their epochs; and, fifth, the yearly range of the temperature. Dovre is situated at a height of 2.064ft. above the sea: all the other stations are situated near the level of the sea.

	January	Narch	April			July	August	Beptember .	October	November	December	Annual	Enochs /	-	Maximum	Epocha	Minima	Epochs	Annual Range

The mean of the year at Christiania, determined by five observations daily, is only 0.05deg, higher than that given by the table. The accordance of the two methods of calculations for the different months is very satisfactory; it is only in the month of December that a difference of some tenths of a degree is found. The difference of 1 3deg, between the Astronomical Observatory of Christiania and the Meteorological Institute is owing to the latter being situated in the middle of the town. Although there is an open space on the northern side of the house, where the thermometers of the Institute are placed, the situation of the Observatory is much more open, and is more suitable for giving the true temperature of the air at the surface of the sur-rounding land. In drawing the isothermal lines from the above table, we find that the isotherms of Dove require but very small corrections. The isotherm of the year for 41deg. (Fahrenheit) goes from Throndhjems-Fiord towards Christiania; on Dove's chart it cuts the coast near Christiansund. The isotherm of January for 32deg, goes from the mouth of the Throndhjems-Fiord to Cape Sindesnes; according to Dove, it is much more to the west. The table shows the effect of the proximity of the Atlantic on the mean temperatures—on the annual ranges-on the epochs of the occurrence of the mean temperature, and of the maxima and minima temperatures.

The following table contains the mean values of the amount of rainfall (and melted snow) at the

<sup>\*</sup> Translated from a paper by Professor H. Mohn, in the "Bulletin de l'Association Scientifique de France," by Mr. J. STAUGHTON HARDING, F.M.S.

different stations. I have added those of Bergen, deduced from a series of seven years' continuous observations, from 1861 to 1867.

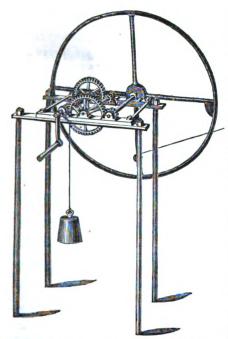

AMOUNT OF RAINFALL IN INCHES.

The maximum is at Bergen, on the west coast, where the mountains rise rapidly above the sea. The mountains at Skudesnes and Mandal are much lower. Aslesund and Christiansund are sheltered from the south winds by the Dovre Mountains. The Scandinavian Alps have their summit towards Aslesund and Christiansund are sheltered the west coast of Norway, and decline very gently towards Christiania and Sandesund, where the west winds are very dry.

## A SELF-ACTING PUNKAH.

THE services of the punkah-wallah—whose manual work in the barracks, hospitals, and private dwellings of India is often unsatisfactory as well as dear—are shortly to be superseded by a very ingenious piece of machinery, the invention of Lieutenant Turnbull, of the 6th Royals. This apparatus, which is shown in the accompanying cut, was recently exhibited at the United Service

Institution, and was approved of by several distinguished Indian officers, as well as by the engineers—civil and military—who saw it in operation.

The mechanism is simple, and its perfect noiselessness will be one of its chief recommendations, the faint ripple of the linen punkah being heard amid the profound silence of the wheels that move it to and fro. A dead weight turning a horizontal shaft gives the desired motion to a slender flywheel with four spokes, a slight jerk of the punkah being caused at each revolution by the plan of making one spoke heavier, at the end next the nave, than either of the other three. This peculiar action imitates, with admirable nicety of effect, the movement of the wrist when the punkah is worked by an attendant. There are 12,000 revolutions of the flywheel, and consequently as many forward pulls of the fan, in eight hours, and this statement will exemplify the great saving of manual labour which the machine accomplishes. It is said, on the authority of a general officer, that the cost of such labour for a month has been,

in the case of one regiment, more than £100. Portability is another of the valuable qualities of Mr. Turnbull's apparatus, which, being taken to pieces, will fit into a shallow box 2ft. square. Heat vieing with that of the tropics is not unknown even in this country, and the adaptation of the self-acting punkah to the wards of our home infirmaries would be no bad idea.

### VERTICAL DRILLING MACHINE.\*

VERTICAL DRILLING MACHINE.

H AVING referred to some of the uses to which the "engine lathe" and the "planing machine" may be applied outside of their legitimate work, let me now mention some of the purposes to which the "upright" or vertical drilling machine may be applied, beside that of simply drilling holes. This machine is constructed in various ways, according to the dimensions and character of the work to be operated upon. The most primitive machine may be denominated the post drill. It consists of a simple casting similar to that of a headstock of a turning lathe fitted to a post in the shop. The spindle is fitted to slide vertically in the boxes, and to rotate at the same time, the rotary motion being given by a pair of bevels and cone pulleys in the usual way, and the vertical motion by a rack and pinion and chain wheel, or a rope is often used instead of a chain. The article to be drilled rests upon the floor, or upon a movable bench. drilled rests upon the floor, or upon a movable bench.

There is another kind of drilling machine which
may be designated the "pedestal drill." This has
a cast-iron pedestal with a broad base, or several legs, resting upon the floor, the pedestal, or body, extending to the ceiling above. The spindle and machinery are mounted upon this pedestal; the heavy machines have a back gear and self feed; they have also an adjustable table, which may be sw ng saide if necessary. This machine has been brought to great perfection; a fine specimen may be seen in the new shop of the Boston and Providence Railway Company in Roxbury.

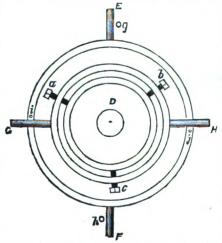

A very useful vertical and drilling machine is that

Railway Company in Roxbury.

A very useful vertical and drilling machine is that of the suspension kind, with a cast-iron table firmly attached to its base. This machine is suspended from the ceiling overhead, having no connection whatever with the floor, thus giving a clear field upon the floor for articles of every size and dimensions, the table at the same time accommodating articles of small dimensions and more accurate work. It is the duty of the makers of these machines to see that the tables are fixed perfectly at right angles with the spindles, and that the tables are so attached that they can be easily swung aside when not in use. A good vertical drilling machine, with a table accurately attached, may be used for boring the hubs of wheels, cutting key ways, chucking tapping nuts, &c., with much facility. For boring and cutting key ways, it is necessary that the centre hole in the table should be bushed with a hardened steel thimble, for a permanent bearing for the boring spindle; the spindle should pass through a leather washer before it enters the steel bush, in order to exclude dust from the bush. The article to be bored may be accurately centred on the table by the placing a "sweep," or arm, on the spindles, and let it revolve close to the rim or edge of the article. When the article is centred, it must be firmly clamped to the table, then the hole may be bored, and a key way, if necessary, may be cut.

In chucking, it is not necessary to confine the article to the table, but simply to hold it from

In chucking, it is not necessary to confine the article to the table, but simply to hold it from revolving; a very simple and efficient chuck for holding articles for this purpose may be made as follows:—Provide two circular pieces of iron, the smallest of which must be large enough to embrace the largest article to be chucked, and the largest some two inches larger than this. (See diagram.)

The smaller ring is provided with three set screws, a b c, for holding the article D, to be operated

" "F. G. W." in the American "Railway Times."

Each of the rings has two fingers, E F G H, projecting from its periphery exactly opposite each other. The fingers of the external ring rest against projecting from its periphery exactly opposite each other. The fingers of the external ring rest against two pins g h in the drill table. These pins must be placed in a line with the centre of the table. The fingers (G H) of the inner ring rest against two pins i j in the rim of the external ring; these pins must be placed opposite each other, and at right angles with the fingers of the external ring. The fingers (i j) of the inner ring should be placed so as not to rest upon the outer ring when the inner ring rests upon the table. This chuck is self-adjusting, and distributes the stress equally upon each of the four pins g h and i j. The conditions for perfect work with this chuck are, that the article to be chucked must be accurately centred, either by the moulder or by means of dividers and a small drill, and that the "reamer" must run true in the spindle. Common flat drills may be used to bring the hole to nearly the size of the finishing tool or "reamer."

### M'LINTOCK'S METALLIC PACKING.

HE importance of a good packing is recognized I wherever the power of steam is utilized, and we think the piston-rod packing, illustrated in the annexed cut, may fairly lay claim to the title of

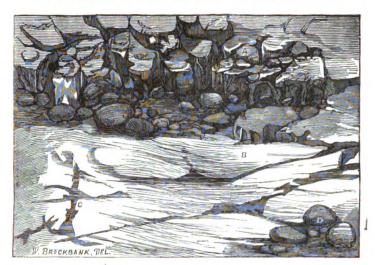

"good." It is the invention of Mr. John M·Lintock, and is now being introduced by Mr. F. Tuxford, of 110, Cannon-street, City. It consists " good." of rings made of alternate layers of linen and india-rubber cement, the whole being compressed in a powerful apparatus. The rings are lined with copper firmly united by claws with the linen. The rings are dense, elastic, and possess many of the best characteristics of a good packing. We are informed that they will last five months in loco motive and twelve to eighteen months in stationary engine work, and we see no reason to doubt the assertion. We have seen testimonials from various eminent firms, which speak to the high character of this packing.

# NITROUS OXIDE GAS TO PREVENT PAIN.

A VERY valuable report (published by Wyman and Sons, of Great Queen-street), has been made after numerous carefully conducted experiments on the human subject and on animals. It states,—1st, that the pure gas, so administered as to preclude the inhaling of any atmospheric air with it, is a powerful anæsthetic—more rapid in its action, although more evanescent in its effects, than chloroform and the other anæsthetics now in general use; 2nd that if its administration were pushed beyond a 2nd, that if its administration were pushed beyond a 2nd, that if its administration were pushed beyond a certain point, it is capable of producing death; but 3rd, that even when death appeared most imminent from its use, the allowing the animal to breathe fresh air, in most cases, brought it rapidly round. It must not, however, be imagined from this that nitrous oxide is an anæsthetic suitable for relieving pain generally. It is suited only to dental and surgical operations which last for, at most, a very few minutes. Its advantages and disadvantages are thus summed generally. It is suited only to dental and surgical operations which last for, at most, a very few minutes. Its advantages and disadvantages are thus summed up in the report before us:—Advantages.—I. The rapidity of its action in producing anæsthesia, the time required for this being from 63 to 81 seconds. 2. The rapidity with which patients recover from its effects, as an anæsthetic; the time required for this being, according to the same table, from 100 to 120 seconds; and patients generally recovering so completely, as well as quickly, as to be able to walk, speak correctly, and write with a steady hand within four minutes from the commencement of inhalation. 3. It is more agreeable to most patients, being, when pure, quite tasteless. 4. It is less irritating to the air passages, coughing or struggling for free respiration being rarely witnessed after its use, except in cases of very nervous persons. 5. The comparative freedom from nausea and vomiting after its use, the average number of cases where actual vomiting has occurred being under 1 per cent. 6. The absence, as a general rule (after the recovery of complete consciousness), of giddiness, headache, and many other unpleasant effects, which are well known to follow the use of chloroform and other anæsthetics. Disadvantages.—I. Its unsuitableness for long operations, owing to the shortness of its anæsthetic effects. 2. Its unsuitableness (or at any rate ineligibility) for operations followed by much smarting and pain, for the same reason. 3. Where very delicate operations have to be performed, the inconvenience

# HEMATITE ORE DEPOSIT.

the operator arising from the muscular twitchings hich often occur from its use. 4. This gas is more oublesome to administer, and requires more emplicated and cumbrous apparatus than other mesthetics do. 5. The inconvenience arising from the trouble of transporting this gas, as compared with the appearance of the expensiveness, and the ther anæsthetics. 6. Its expensiveness, and the ifficulty of procuring it in a pure and efficient state or use at all times, if wanted on an emergency.—Scientific Opinion."

'HE HEMATITE IRON ORE DEPOSITS OF WHITEHAVEN: NOTES ON THE ALDBY LIMESTONE, CLEATOR MOOR.\*

BY W. BROCKBANK, F.G.S.

THE mountain limestone of the Cleator district forms an assessment forms an escarpment to the valley of the iver Ehen, from Egremont round the base of Dent lell, towards Cockermouth. It rests upon the old lay slate of Skiddaw and Dent, and is the outcrop if the Whitehaven coal field. It contains most ctensive and valuable deposits of hematite iron re, and is therefore an interesting subject for tudy in any aspect which will throw light upon a question of the origin and deposition of the any aspect which will throw light upon be question of the origin and deposition of that aluable mineral. The general character of the ematite deposits in this limestone was briefly setched by the writer in his remarks to this ociety, December 10, 1867, and which were rinted in the Proceedings, p. 59-61. The object f the present communication is briefly to describe he section of mountain limestone exposed in the uarries of the Whitehaven Hematite Iron Comany, at Aldby, on Cleator Moor, and its surface as ffected by diluvial and glacial action—believing hat both these points have a considerable bearing pon the subject of the occurrence of hematite ron ores.

About an acre of the surface of the limestone is t present exposed, having been cleared of from ift. to 8ft. of the till or boulder clay which covered This clay is of the character well known to us a the neighbourhood of Manchester, having oulders of porphyry, granite, greenstone, clay, late, and the other well known characteristics of he drift, and is believed by the writer to have lad the same or a similar origin, viz., from the nountains above Ravenglass, near Wastwater and Devoke Water. The easterly side of this large imestone surface bears a striking resemblance to the tops of some of the Yorkshire hills—such as he Moughton Fell, the flanks of Ingleborough, or the mountain limestone summits near Grange in Cartmel-being deeply fissured in every direction. On these fissures being emptied of the till by which they have been filled, they are found to contain the roots of ferns or other mountain plants still attached to the crevices of the rocks, just as we see similar clefts abounding in plants on our mountain tops in this day.

About half the area is thus fissured, and when

About half the area is thus insured, and when the crevices are not filled with till they are found to contain hematite ore. Most of them have, however, been much waterworn, being andercut and hollowed out into basins and arches of every form. Passing westwards across the cleared surface, we come to a most marked illustration of

\* Read before the Manchester Literary and Philosophical Society.

glacial action. The projecting masses have all been cut away, and the surface, for some half acre one cut away, and the surface, for some half acre in extent, planed smooth by ice, the floor being evenly cut into long undulations, deeply scratched in long clearly marked striations. The markings run nearly S. to N., and as the boulders are of greenstone, porphyry, granite, syenite, and clay slate, of similar nature to the rocks now existing in the granitic and synetic district of Birker Moor, about Devoke Water and Wastwater, there is little doubt that they came from that locality, lying, as it does, nearly south, in the direction indicated by he striations. Several veins of hematite ore are exposed upon this polished surface, as shown in the accompanying sketch of limestone surface at Aldby Quarry, in which A is the fissured limestone after removing the till; B, eroded surface; C, vein ore; D, boulders of granite, syenite, &c.
The quarry presents a very fine section of lime-

stone rock from its eastern escarpments towards the Ehen valley to its junction with the lower coal measures, at the westerly corner of the quarty, and from 50ft, to 70ft, in height. The limestone beds are much contorted and intersected by faults showing a very disturbed and irregular stratifica-, tion. The easterly escarpment, sloping towards the river Ehen, is made up of a breccia of hematite ore and limestone, in large irregular blocks, cemented together into a compact mass. It was so rich with ore at the surface, as to be worth working, and an open quarry was commenced, and a large quantity removed, but the impurity of the product soon led to its abandonment. It is very evident that this face of limestone was at one period covered with a large deposit of hematite ore, since denuded. Wherever a fault or fissure occurs in the face of the quarry it is filled with ore, evidently from above. Many of these veins of ore have appeared so rich as to induce the miners to follow them by shafts; but no large pockets rewarded the search, the main limestone eing too regular and compact to admit of any large masses. It is, however, quite evident that if any large cavities had occurred, they would have been filled in from above with iron ore, as is the case at the neighbouring mines of Gutterby, Bigrigg, Parkside, &c.

We have, therefore, evidence in this quarry First, of a deposition of hematite iron ore by water, after the limestone had been uplifted into its present position, or nearly so; and, secondly, the denuding action of running water, and afterwards of the erosion by drift ice, probably coeval with our own boulder drift, and from the same centre of glacial action. Under more favourable circumstances, these powerful agents might have been instrumental in depositing large masses of hematite ore, as there is abundant evidence that this has tite ore, as there is abundant evidence that this has been the case within a very short distance from Aldby—large masses of iron ore having been worked by open quarry, lying in exactly similar positions as the small crevice-filled cavities first described. It is also very evident that these denuding agents have likewise been instrumental in removing large quantities of ore previously de-posited, and the outliers of limestone capping isolated prominences in this neighbourhood, testify to the great extent of denudation which we may reasonably suppose took place at the period indicated by the eroded surface of the Aldby limestone.

bank, states that the chief portion of the vegetation referred to in the preceding paper, consists of dark-coloured fragments of the stems of a dicotyledonous plant which seem to have been broken sharply off while growing in situ. They have the general appearance of rotten sticks, and in their fresh condition are very soft and friable, yielding readily to the knife, but with exposure to the air they dry and become much harder. They appear to have belonged to a shrubby plant of no great size, the stems of which would range between half and three-quarters of an inch in diameter. internal portion of the stems has almost entirely disappeared, and in the few fragments examined, there are no traces of any woody layers, medullary rays, or central pith. The portions preserved rays, or central pith. The portions preserved consist of true bark, which is made up of two layers:—an exterior layer, or periderm, which is in a good state of preservation; and an interior fibrous portion, or liber, made up of short rectangular cells, which form layers of considerable thickness.

All the woody fragments examined belonged to aerial portions of the plant, but there are no re-mains of the leaves borne by these stems, and it would be very desirable that they should be sought for in the lower portion of the overlying clay, as they would be very helpful towards determining the species. If a conjecture might be hazarded, from the nature of the fragments examined, as to the particular plant of which they formed a part, I should refer them to some species of Betula (birch). There was a single piece of woody matter looking like the rhizome of a fern, but the presence of scalariform tissue failed to be detected in it, and the fragment was too small to draw a definite conclusion from. Intermixed with the stems referred to above are the leaves of some cryptogamous plant, like those of a hypnum, and formed of square shaped transparent cells; and embedded in the earthy portions which make up the remainder of the mass are a few well preserved thread-like roots, which are white in colour, cylindrical in shape, only slightly branched, and containing well defined vessels.

# MANCHESTER BOILER ASSOCIATION. CHIEF ENGINEER'S MONTHLY REPORT.

THE last ordinary monthly meeting of the executive committee of this Itive committee of this Association was near at the offices, 41, Corporation-street, Manchester, on Tuesday, January 12, William Fairbairn, Esq., C.E., F.R.S., LL.D., &c., president, in the chair, then Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract: tive committee of this Association was held During the past month 373 visits of inspection have been made, and 800 boilers examined. Of this number of boiler examinations, 574 have been external, 14 internal, 8 in the flues, and 204 entire, while in addition 9 boilers have been tested by hydraulic pressure. In these boilers 125 defects have been discovered, 11 of them being dangerous. Furnaces out of shape, 3-2 dangerous; fractures, 15; blistered plates, 7-1 dangerous; internal corrosion, 19-2 dangerous; external corrosion, 17 —1 dangerous; internal grooving, 17; external grooving, 3; feed apparatus out of order, 4; water gauges out of order, 6—1 dangerous; blowout apparatus out of order, 12; safety valves out of order, 3; pressure gauges out of order, 7; boilers without glass water gauges, 4-dangerous; without pressure gauges, 1; without blow-out apparatus, 2; without feed back pressure valves, 5.

On the present occasion, I have two explosions to report, by which four persons were killed and three others injured. Neither of these explosions occurred to boilers under the inspection of this Association. The following is the statement of explosions from November 21, 1868, to December 31, 1868, inclusive:—December 2, vertical (internally fired), 1 injured. December 11, vertical marine (internally fired), 4 killed, 2 injured. Total, 4 killed; 3 injured.

Mr. Fletcher reports that another feed water heater or economizer has exploded, which makes the third that has recently failed in this way. This is something quite novel and surprising, as this is something quite novel and surprising, as this apparatus had previously been considered as incapable of explosion. Since these economizers prove of so much service, and are so generally adopted, the question of their safety is one of general importance. The explosion referred to occurred in France, on Saturday, December 26, and by it three persons were killed and others injured. The distance from Manchester at which this took place, combined with the pressure of this took place, combined with the pressure of Mr. C. Bailey, in a letter addressed to Mr. Brock-lother duties, prevented a personal examination,

which would otherwise have been made, on account of the importance of the question, but Mr. Fletcher expects shortly to be in possession of the details, which shall be reported as soon as possible. In the meantime, the suggestions given in the report for October last, when referring to the recent economizer explosion, may be repeated, viz., that the following precautions should be adopted for guarding against similar disaster, whether from steam or gas. In the first place, the safety valves on the economizers should be at once examined to see whether they are in working order, while it may be pointed out that a safety valve of external may be pointed out that a safety valve of external dead weight pendulous construction, without wing or spindle, similar to those in use on many of the members' boilers, is less likely to become gagged by incrustation than the ordinary lever safety valves boxed in out of sight, which are generally used; while, in the second place, the flues should be examined to see that there are no void chambers in which gas can accumulate, and care should be taken when either the economizer or bye-flue is shut off, that the damper at the entrance be closed as well as that at the chimney.

The attention called to the subject of smoke prevention, by the late experiments, conducted on this subject at Wigan, by the South Lancashire and Cheshire coal owners, and fully reported by us, has led the Manchester Boiler Association to add to its staff the trained stoker, who was engaged throughout the whole of the experiments just referred to, the object being that he might visit the works of the members, and assist their stokers in introducing a more smokeless system of firing. He has now been engaged in this way for about three months, and the table above may be of interest as showing the results arrived at.

From the above table it will be seen that the Association's stoker has visited thirteen of the Association's stoker has visited thirteen of the members' works, and operated upon sixty-three boilers, consuming per week 1,085 tons in the gross, and on an average, 17½ tons per boiler; while the main rate of combustion per square foot of fire grate per hour has been 18¾1b. Under these conditions, the average result has been realized of about 12½ minutes of very light smoke, 21 minutes of brown, and one-third of a minute of black per hour, which is certainly very much below the amount emitted from chimneys generally. The conditions under which the trials were made were not by any means the most favourable for success. In some cases, the doors had no perforations; in many, the area was too limited; while some of the firegrates were 7ft. in length, which is too long. While no doubt more remains to be done too long. While no doubt more remains to be done to complete this movement, yet it has been seen that much can be accomplished by careful firing alone, coupled with the admission of a little air at the firedoor, which shows the importance of having all firedoors fitted with suitable sliding grids on the outside, and perforated box baffle-plates on the inside.

# HYDRAULIC BUFFERS.

TO THE EDITOR OF THE "MECHANICS MAGAZINE."

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Your magazine of November 6, 1868, contains an interesting suggestion by Colonel Clerk, R.A. for the employment of hydraulic buffers on railway trains; and my experience with water cylinders induces me to believe that the suggestion is well worthy of an experimental trial, and that the result would be found satisfactory. It is hopeless to expect that any buffer can be found which will entirely remove the dire effects of a railway collision, but I am convinced that the effects of collisions would be much lessened by the employment of hydraulic buffers; while many of those accidents to passengers in railway stations, caused by the recoil of spring buffers, would not occur. The idea to me is not a new one for I remember well the ingenious little model, shown would not occur. The idea to me is not a new one for I remember well the ingenious little model, shown to me by Mr. John Hanson, of Huddersfield, also the to me by Mr. John Hanson, of Huddersfield, also the circumstances attending it, as detailed by him in your magazine of November 20, 1868. I had that model several years in my possession, made many experiments with it, and satisfied myself that the idea was a good one. In thinking over the matter and its reference to Mr. Hauson, it brought to my mind a thing which is not generally known, viz., that the "needle gun" was invented by him in England. Proof thereof may be found in Golden and Hauson's natural, dated November 1, 1841.—1 am Sir yours patent, dated November 1, 1841.—I am Sir, yours, &c., C. E. Amos.

5, Cedars-road, Clapham-common, S. January 29.

## NICKEL PLATING.

NICKEL PLATING.

SIR,—I should feel much obliged if you, or any one of the readers of your paper, can give me, through the medium of your journal, information, or state where I can obtain such information, on the subject of nickel plating. Is it a new or old invention? If the former, whether it is patented, and number of patent? Is the nickel, after plating, subject to oxidization. Any further information on the subject will be thankfully received.—I am, Sir, yours, &c.,

F. O.

the subject will be thankfully received.—I am, Sir, yours, &c.,

London, February 1.

[There is no patented process for depositing nickel on other metals now in existence, or ever has been, that we are aware of. We have seen the nickel deposited from various solutions. For example, from a solution of nickel cyanide in potassium cyanide; from an aqueous solution of nickel chloride, and from an aqueous solution of nickel sulphate. The cyanide solution gives the best coloured metal. and from an aqueous solution of nickel sulphate. The cyanide solution gives the best coloured metal, but it works badly. The sulphate solution works the best; nickel does not oxidize either in dry or damp air; nor does sulphuric acid or hydrochloric acid act readily upon it. As to the proper solution to be used, that depends entirely on the metal to be coated. Nickel, when deposited has much the appearance of platinum.—ED. M. M.]

the firebars being reduced from 9in. by 4in. to 6in. by 2½in., so as to work in the tube. It is found that these bars burn rapidly, and do not last nearly so long as those used in Juckes' system applied to eggend boilers, and which are 9in. by 4in. I would thank you to say whether you think the cause of burning is through reducing the size of the firebars, or because of the returning firebar coming so near the upper firebars. The air having to pass through the returning bars becomes increased in temperature before reaching the fire.—I am, Sir, yours, &c., Wigan, Feb. 3. Enquirem, M. [The result of which our correspondent complains is doubtless due to both the causes mentioned—viz., the reduction of the bars and the increase of temperature. Besides, this application of Juckes' system is hardly a fair test of the principle, to which no blame can attach if failure occurs under such conditions.—ED. M. M.] the firebars being reduced from 9in, by 4in, to 6in.

### SUGAR AND STARCH MACHINERY.

SUGAR AND STARWH MAN HYBERT.

SIR,—Can you, or any of your readers, oblige mo with any information on the following points:—

1. Who are the manufacturers of Wilde's patent for purifying or crystallizing sugar by electricity?

2. Who are the manufacturers of machinery for making starch from notatees and corn?—I shall be making starch from potatoes and corn? I shall be much obliged if you can help me in the matter.—
I am, Sir, yours, &c., ENQUIRER.

### TOBACCO MACHINERY.

TOBACCO MACHINERY.

SIR,—Referring to the notice of machinery at Messrs. Wishart and Lloyd's, in your last impression, allow me to state that the manufactory was laid out and fitted according to my directions, and under my immediate supervision as consulting engineer for Messrs. Wishart and Lloyd, and that I superintended the arrangement of the machinery, for the successful carrying out of which so much credit is due to the makers.—I am, Sir, yours, &c., EDWARD FIELD. EDWARD FIELD.

Chandos Chambers, Adelphi.

### Meetings tor the Bleek.

TUES.—Royal Institution.—Mr. Westmacott, on "Fine Art," at 3 p.m.

The Institution of Civil Engineers.—Discussion on "The Mauritius Railways, Midland Line;" and Professor Ansted, F.R.S., on "The Lagoons and Marshes of Certain Parts of the Shores of the Mediterranean," at 8 p.m.

WED.—Civil and Mechanical Engineers' Society.—Mr. G. H. Royce on "Our Railways, their Condition and Prospects," at 8 p.m.

THURS.—Royal Institution.—Or. M. Foster on "Involuntary Movements of Animals," at 3 p.m.

Fat.—Royal Institution.—Colonel Jervois on "The Coast Defences of England," at 8 p.m.

Royal United Service Institution.—Major C. Adams, Professor of Military History, Royal Military College, on "The Italian Campaign of 1866," at 3 p.m.

SAT.—Royal Institution.—Professor Odling on "Hydrogen and its Analogues," at 3 p.m.

THE MANUFACTURE OF WATCHES AND CLOCKS.—A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons acid act readily upon it. As to the proper solution to be used, that depends entirely on the metal to be used, that depends entirely on the metal to be conted. Nickel, when deposited, has much the appearance of platinum.—Ed. M. M.]

SMOKE CONSUMPTION.

SIR,—The subject of rotary furnaces, applied to tube boilers for consuming smoke, &c., is at present occupying considerable attention in this town.

Juckos' furnace has been applied to a boiler tube it to the notice of the intending purchasor.—| Advr. |

# Habal, Military, and Gunnery Items.

THE American steamboat "Clyde" was wrecked in Red River on the night of the 12th of January. Six persons were killed and 25 injured by the disaster.

THE last new plaything of the French War Office is a kind of infernal machine, which in one minute's time can propel 1,500 bullets to a distance of 1,200 metres (about 1,300 yards).

WE—"Broad Arrow"—believe that notwithstanding the great reduction contemplated in the number of subaltern offices, those gentlemen who have actually passed their examination will shortly be provided with commissions. As some anxiety has been expressed regarding the disposal of these gentlemen, we are glad to be able to make this announcement.

Some of the large shipbuilders at Poplar have received orders for the construction of vessels for the Turkish and other governments. Messrs. Wigram are about to lay down two passenger steam vessels for the Portsmouth and Ryde Steam Packet Company, to be ready for traffic next summer. They are to be named respectively the "Duke of Edinburgh" and the "Princess Alice."

A MEMORANDUM has been issued for the information of officers and men employed in the dockyards, who are likely in future to become candidates for examination for promotion, that a much larger acquaintance than heretofore with iron shipbuilding and with the properties and peculiarities of steel plates and rivets will then be required of them. The Chief Constructor's new work will prove of great assistance to these candidates.

A DESPATCH from Fortress Monroe states that on the 13th of January at that place General Barry presented to Captain Robert Creighton, formerly master of the British ship "Three Bells," a superb gold medal, voted him by Congress for his gallant services in rescuing the survivors of the wrecked American steamer "San Francisco," some time ago. The presentation was made by express instructions of the War Department. Captain Creighton now commands the West India Royal mail steamer "Venezuela."

THE "United Service Gazette," touching on naval economy, says that matters are really becoming serious, and Mr. Childers seems to be as much in earnest as the player who, as Mr. Dickens describes, went so entirely into his part that in playing "Othello" he blacked himself all over. The Admiralty in visiting Chatham Dockyard had no guard of honour, and went to the yard in cabs. Our correspondent (though we are constrained to confess that, on this one occasion, to speak clearly, we do not believe him), says that all five went in one cab, and that a lively discussion with the driver on the subject of an extra sixpence took place at the Dockyard gates.

We have to record the death of an old man-of-war's-man, who was perhaps the last surviving seaman who took part in the brilliant engagements of St. Vincent and the Nile. The old man, who was named Stephen Watler, expired on Friday, the 22nd ult., at his lodgings in Margate. He was in his 97th year, he having been born in July, 1772. He served under Lord Howe in the memorable action of 1794, for taking part in which engagement he was rewarded with a medal, which he retained up to the day of his death. He also served under Lord Nelson, and took part in the naval engagement of the Nile as gunner's mate on board the "Barfleur."

gunner's mate on board the "Barfleur."

[ON Saturday last, the tank vessel "Dispatch," built for H.M. Government, by Messrs. Maudslay, Field, and Son, was successfully launched from their works at East Greenwich. Her dimensions are:—Length between perpendiculars, 115ft.; breadth, extreme, 22ft.; depth. 10ft.; builder's measurement, 250 tons; and engines of 40-horse power. She is destined for the service of the Royal William Victualling-yard at Devonport, for carrying fresh water and provisions to the fleet. The tanks are capable of carrying 150 tons of water; the hull is divided by seven bulkheads into eight compartments; the auxiliary steam engine and pump in the engine-room are so arranged as to draw from either of the tanks independently, and the ship's pumps are also arranged to draw from the tanks and from each of the compartments.

The states of the island of Jersey have in contemplation the supplying of a very much needed aid for safe navigation on a dangerous part of the south-west coast of the island—known as the Corbierre Rocks—by the erection of a lighthouse thereon. By this means vessels will be enabled safely to pass the treacherous spot, which has been the cause of the destruction of many a fine vessel; and the mail packet will often be enabled to reach Jersey at night time, when detained by stormy weather, instead of being obliged to stay all night at Guernsey, as they are now frequently compelled to do, to avoid the dangers of approaching the island without the muchneeded light to indicate the vicinity of the dreaded

Corbierre. The states only wait for the consent of the Trinity House, and an undertaking that the light shall be entirely under the States' control.

THE "Wellesley," training ship, is now illuminated with gas. It is conveyed under water by means of elastic tubes. There was no reason why it should not have been manufactured on board, as is to be done in H.M.S. "Monarch," but the gas being within 200ft., it was thought best to take it from the shore. Lighting ships with gas appears to be no novelty, inasmuch as more than forty years since, the steamer "Duke of York," which was then chartered by Government, and employed in carrying mails and passengers between London and Portugal, Spain and the Mediterranean, was lighted with gas. It was not made on board, as in the case of the "Monarch," but kept in iron bottles, one of which was screwed on to the main, and when the gas contained in it was consumed, a fresh bottle was substituted. The "Duke of York" was afterwards purchased into the Royal navy, re-named the "Messenger," and is, or very lately was, a coal depot off Woolwich.

# Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending January 30, was 5,103. Total number since the opening of the Museum, free daily (May 12, 1858), 1409.657

In a cave at Rock Island, Illinois, the statue of an Indian maiden has been discovered. It has a solid copper pedestal, 71t. high, and obelisk of solid brass. Other Indian curiosities have been lately discovered in the same vicinity.

On the night of January 13 there was an extensive fire in Philadelphia, burning one of the finest blocks of warchouses in the city, and involving a loss of 1,000,000 dollars. Two young men perished in the flames.

At the meeting of the Society of Engineeers, held on the 1st inst., Mr. F. W. Bryant, President, in the chair, the following candidates were balloted for and duly elected Associates:—Messrs. C. C. Gibbons, of 35, Great George-street, and Alfred Rubery, of 12, Dowgate-hill.

The foreign trade of the Colony of Victoria continues to show an increase. In the first eleven months of 1868 the imports amounted in value to £11,391,938, an increase of £1,416,503 over the corresponding period of 1867. The exports amounted to £12,814,750, an increase of £2,625,211.

At a meeting of the Carlisle Angling Association, held yesterday week, it was stated by the committee in their report that the spawning beds in the river Eden are "literally crowded with salmon," and the oldest watchers on the river never saw so many salmon in the river as there are this year. Similar reports come from the Nith, in Dumfriesshire.

THE Government of the Emperor Alexander has raised Kiew, chief town of the province of Little Russia, to the rank of third capital of the empire, placing it next to St. Petersburg and Moscow. In consequence of this resolution an Imperial palace is to be constructed there without delay; and the Minister of Finance has received orders to place at the disposal of the architects the necessary sums.

WE understand that the new Blackfriars Bridge is definitely to be opened on the 24th of next May. There is a peculiar fitness about the choice of the date. On the 24th of next May her Majesty will complete her 50th year, and, by a curious coincidence, it also happens that that day will also be exactly the hundredth anniversary since the opening of the old Blackfriars Bridge in 1769.

THE number of visitors to the South Kensington Museum during the week ending January 30, 1869, was—on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 15,791; Meyrick and other galleries, 3,352; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 2,050; Meyrick and other galleries, 324; total—21,517. Average of corresponding week in former years, 10,184. Total from opening of Museum—8,116,885.

THE Society of the Friends of the Arts of the Moselle have decided that an exhibition shall take place at Metz this year. It is to open on May 1, and to close on the 20th of the same month, in order that the artists exhibiting there may have the opportunity of sending their works to the Strasburg exhibition, which opens soon afterwards. The Metz exhibition is open to artists of all nations, and works are to be sent in to the Hotel de Ville of Metz five days at least before the opening day.

A LETTER from Wolverhampton gives a description of an apparatus, provisionally patented by the Wolverhampton Corrugated Iron Company, the missance which arises from galvanizing works, but regarded as extremel which is capable of very extensive application, and the necessity for which will increase as chemistry for blasting purposes.

enlarges, as it is rapidly doing, its industrial applications. The process appears simple, and is spoken of as most effective.

At the monthly ballot of the Institution of Civil Engineers, on the 2nd inst., the following candidate were balloted for and duly elected:—As Members, Messrs. J. H. W. Buck, T. Dale, P. Greck, and H. J. Wylie. As Associates, Messrs. J. Bowden, A. M. Fowler, C. Hart. B. M. de Michele, J. Musgrave, E. W. Preston, A. L. Sacre, H. T. H. Siccama, A. H. Strongitharm, and J. W. Wilson. Mr. J. P. Van der Meulen was admitted as a Student.

On Thursday night week the Rochester bridge of the London, Chatham, and Dover Railway, caught fire. It crosses the Medway, and is of very wide span, the lower portion being constructed of massive wooden beams. The fire had gained considerable hold of the bridge, but owing to the close proximity of the water and other appliances, it was extinguished without any extensive damage been done. The same bridge has previously been on fire three or four times, as supposed from the fire dropping from the ashpan of a passing engine.

dropping from the ashpan of a passing engine.

At the general monthly meeting of the Roya Institution of Great Britain, held Monday, Feb. 1 Mr. W. R. Grove, Q.C., in the chair, Messrs. Edward Armitage, Geoffrey Bevington, Frederick Leighton, Frederick Nettlefold, Frederick J. Toulmin, R. O. White, William Edward Wilson, Philip Wright, and the Master of Lindsay, were elected Members of the Royal Institution. The special thanks of the members were returned for the following additions to "the Donation Fund for the Promotion of Experimental Researches":—Mr. Alfred Davis (third donation), £21; W. D. (third donation), £5 5s.

ANOTHER episode has just occurred in connection with what is popularly known as the Edmunds' scandal case. The pending action for libel brought by Mr. Leonard Edmunds against Mr. Greenwood, the solicitor to the Treasury, and which was to have come on for trial in the Court of Common Pleas by a special jury about this time, will not now be tried. At the last moment, all questions between Mr. Edmunds and the Crown, including the present action for libel, are referred to a court of arbitration to sit in public. The terms of the arbitration have been in agitation for the last eight months, and at last they are agreed to.

A NEW mode of tolling great bells has just been applied to the 4½ ton bell lately cast by Messrs. Taylor, of Loughborough, for Worcester Cathedral, and recently hung there. The bell has been hung on a new plan, which, with the clock and a peal of twelve bells, is designed by Mr. Denison, Q.C., and gives a new effect to bells which are too heavy to be rung in the usual way. The gudgeons, or pivots, instead of being round, are wedged-shaped, like those of a scale beam, and roll on hard brasses very slightly hollowed. The friction is thereby made so little that this great bell can be tolled easily by one man with one hand.

THE Metropolitan Street Tramway Bill came before Mr. Palgrave, one of the examiners of standing orders, recently, who, after the necessary proof had been given, decided that the standing orders had been ecomplied with. The Pimlico, Peckham, and Greenwich Street Tramway Bill has also passed standing orders, and was considered at a special meeting of the Greenwich District Board of Works, who, after hearing explanations from the engineer of the company, and examining the models of the rail proposed to be laid, approved of the bill, and instructed their clerk and engineer to agree to clauses with the company, and petition in favour of the bill.

A PROMINENT citizen of Detroit, largely connected with railways, is now causing to be made a thorough examination of the river, for the purpose of ascertaining the feasibility of tunnelling it. The project of a tunnel under the Detroit river has been discussed from time to time, but nothing looking to practical investigation of its feasibility has hitherto been attempted. If it is practicable to build a tunnel, it will prove an important link in the great central railway route between the West and the East. The examinations are being made, and we (American "Railway Times") understand are to be under the supervision of Mr. Chesbrough, the engineer of the Chicago tunnel, waterworks, &c.

Some successful experiments have lately been made with dynamite at a quarry at Oester Acker, in Norway, according to the "Mining Journal." Three shots were fired—the second, and principal one, being on a very large scale. The bore-hole was 21ft deep, and 1½ in. in diameter; 15lb. of the strongest dynamite, containing 75 per cent. of nitro-glycerine, being employed as the charge. It was estimated that about 264 cubic yards of earth were displaced; but it was not considered that the whole power of the charge had been utilized, and another charge of only 2½ lb. of dynamite produced a proportionably still greater result. On the whole, the experiments were regarded as extremely satisfactory, and as proving that dynamite is decidedly cheaper than gunpowder for blasting purposes.

# Patents for Inbentions.

# ABRIDGED SPECIFICATIONS OF PATENTS

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2253, 2288, 2292
BUILDINGS AND BUILDING MATERIALS—2257, 2273
CHEMISTRY AND PHOTOGRAPHY—2261
CULTIVATION OF THE SOIL, including agricultural implements and machines—2279, 2297
ELECTRICAL APPARATUS—2271
FIBBOUS FABRICS, including machinery for treating fibre pulp, paper, &c.—2260, 2270, 2286, 2289, 2294, 2296
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—None.

GENERAL MACHINERY—2247, 2255, 2256, 2258, 2263 LIGHTING, HEATING, AND VENTILATING—None. METALS, including apparatus for their manufacture 2265, 2293

W165, 2293
MISCELLANEOUS—2246, 2251, 2259, 2262, 2262, 2267, 2272, 2276, 2278, 2280, 2282, 2283, 2285, 2287, 2290, 2295
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2248, 2252, 2281
SHIPS AND BOATS, including their fittings—2268, 2275, 2291

2291 STEAM ENGINES—2254, 2269 WARFARE—2249, 2284

2246 G. Moulton, Manchester. Engraving. Dated July 17, 1868.

This relates chiefly to the pentagraph engraving machines employed to engrave or trace patterns or designs on the surfaces of cylindrical rollers, and consists, principally, in an improved method of effecting the reversal of the cutting tools, and is applicable more particularly to machines having but one row of tools, and of effecting the "stepping of the pattern" or the changing of the relative positions or portions of the complete design. In one arrangement, the tools are reversed by connecting the tool bar or carriage to an endless band, or to a band or bands acting as an endless band the band passing around drums or pulleys, so that the two opposite portions of the band move in opposite directions, the tool bar being connected to one portion of the band or to another portion of the band move in opposite direction, according as the tools are required to meve in the same direction as the tracer, or in a direction contrary thereto. The ends of the band are attached to a drum or pulley, which is actuated by an intermediate travelling bar, upon which the tool bar is mounted, the intermediate bar deriving its motion from the diminishing pulley of the pentagraph, the tool bar and the intermediate bar being mounted upon rollers in the usual manner. In another arrangement for effecting the same object, the band actuated by the tracer carriage is passed twice around or partly around each of the end carrier pulleys, so as to present two free portions of the band, moving when actuated in contrary directions, the tracer carriage being connected to either of the portions, according as the tool bar is required to move in one direction or the other. To connect the tool carriage or tracer carriage with the band, the patentee prefers to employabolt or screw, acting upon clips, in such a manner as that when the screw is turned in one direction, a clip is tightened upon a portion of the band. To effect the "stripping" or "changing," the screw is turned into an inte

2247 W. J. Ellis, Barnsbury. Cranes. Dated July 17,

1868.

This consists, first, in the employment of a lever or levers of the first or third order, operated by means of a screw jack, hydraulic, air, steam, or any other kind of press or machine, which may be employed for the purpose of the concentration of the force to be used; and, second, in the construction of swing cranes, which depend for support on their foundations to prevent their being overturned, with a holding-down bolt as centre pin or axis in place of the massive post hitherto employed.—Patent completed.

2248 E. FUNNELL, Brighton. Railway signalling. Dated

2248 E. FUNNELL, Brighton. natural segments.

July 17, 1868.
The principle of this invention is to give distant oscillations to a disc, combined with the striking of a bell, by a train passing over a treadle, in order to give warning to a signalman at a distance that the train is approaching. This is accomplished by a treadle in connection with wheelwork and an electrical apparatus, the whole to be made to act automatically.—Patent completed.

made to act automatically.—Patent completed.

2249 C. P. STONE, Dorset-square. War vessels. Dated
July 17, 1868.
The fighting capabilities of a vessel of war is developed
by providing a means of rapidly sinking the greater portion of the hull usually above the water, so as to present
less surface to attack. The patentee proposes to divide the
length of the vessel into sundry equidistant water-tight and
air-tight compartments, and to place a series of cylindrical

or polygonal cisterns in contiguity, and equilibriating the ship's centre of gravity, the spaces between the cisterns to be in communication with the space between the skins or air chamber. The water is to be admitted into each cistern by a sluice valve. These cisterns can be used to hold cargo or stores when not required for immediate use.—

Patent abandoned. Patent abandoned.

Patent abandoned.

2250 A. Woollan, Notting Hill. Watch protector. Dated July 17, 1868.

This protector or fastener is made of one piece of metal somewhat in a T shape—that is to say, having two horizontal and one vertical arms. The vertical arm of the T is bent at about half its length, so as to form a hook. In use, the fastener is secured to the article of apparel, or within a pocket, and a hinged catch is moved so as to release the hook; the ring or hoop of the watch is passed into the hook and the hinged catch fastened.—Patent abandoned.

2251 J. DUGUID Glassow. Paper. Dated July 17, 1868.

abandoned.

2251 J. Duguid, Glasgow. Paper. Dated July 17, 1868.
Webs of wire cloth are employed in place of felt on the rollers or cylinders, over which the paper or pulpy material passes on its way from the paper-making machine. The wire webs are made shorter than the felt webs at present used, they do not absorb moisture from the paper, and they do not require so long a travel to give them time to dry. By the use of wire webs, the injurious effects due to the moisture of travelling felts are avoided. Another advantage is that the wire webs, being free from shrinkage, may be made much narrower. The wire webs can be woven in looms and put on in the same manner as the felt webs.—Patent completed.

2252 W. J.C. Mug, Westminster. Permanent way Dated.

2252 W. J.C. Muir, Westminster. Permanent way. Dated

webs.—Patent completed.

2252 W. J. C. Mur, Westminster. Permanent way. Dated
July 17, 1868.

This consists, in the first place, of a sleeper made of cast,
wrought, or malleable iron or steel, with a horizontal flanch,
carried wholly or partly round its outward perimeter, and
so much above the base of the sleeper as to leave a vertical
edge or rim round the base under the flanch for ensuring
a perfect gripe, on or in the ballast, the normal transverse
section of the body of the sleeper, exclusive of projections, being a semiellipse, or the half of any other curve
resulting from a conic section. In the second place, it
consists in the application of this sleeper to a flat bottomed
rail, at the same time securing elasticity in the bedding of
the rail, without the interposition of wood or other packing, this being effected by casting on the sleeper two
narrow shoulders or fillets running along its upper side or
crown, their distance apart being such that the edges of
the foot or flanch of the rail shall rest on the fillets, leaving a hollow space under the middle of the rail, into which
it may deflect under pressure or concussion. In the third
place, it consists in a method of holding the rail to the
sleeper by the employment of a gripping piece or clip of
iron or steel, so formed as to fix also the tie-bar, which
connects a pair of sleepers, the tie-bar having a projecting
head, hole, siot, notch, or groove at or near each end, and
the gripping piece being held firmly in place by a key or
wedge.—Patent completed.

2253 C. J. Galloway and C. H. Holl, Manchester.

Patlers.

connects a pair of sieepers, the we-bar having a projecting head, hole, siot, notch, or groove at or near each end, and the gripping plece being held firmly in place by a key or wedge.—Patent completed.

2253 C. J. GALLOWAY and C. H. HOLT, Manchester. Boilers. Dated July 17, 1868.

According to one arrangement, the boiler is divided into two parts. The upper portion is supported over the fire space, the other is of a ring form, placed below the main portion, and connected thereto by tubes. The ring is adapted to receive the sediment, which may be removed therefrom by suitable taps or outlets. The upper and under surfaces of the upper portion of the boiler are connected together by means of tubes, which are considerably larger in diameter at the upper than at the lower end, and serve both as stays and flue passages. The diameter of each tube under its upper flange is equal to the outer diameter of the flange at the lower end thereof. To prevent the too free passage of heated products up these flue passages, a ball or hollow water chamber is connected above and below with the water in the boiler by tubes. The upper portion of the boiler may be continued down and serve as a jacket or water space surrounding the fire. In heating the water for the supply of steam boilers by means of water pipes applied in the flue, it is usual to apply dampers to regulate the draft, and the object of one part of the improvements in heating the water is to obtain a subdivision or more equal distribution of the currents of heated products to act on the feed water by employing a number of small valves, or dampers, or passages which are capable of regulation, in place of a large one. An upand-down motion is given to scrapers for clearing the external surface of the feed water heating pipes by means of external and internal gearing, or what is commonly called the mangle motion.—Patent completed.

2254 W. and W. T. EADES, Birmingham. Obtaining power. Dated July 17, 1868.

Two shafts are employed, upon the ends of which are secured two pai

ings, which also carries the drum upon which the chain rope is wound.—Patent abandoned.

2255 A. Brown, King William-street. Liquid meters. Dated July 17, 1868.

The patentee proposes to construct a vessel or cistern with four compartments, two of which contain floats nearly as large as the vessels in which they work, but not nearly so deep, the floats being quite independent of each other. In the third compartment is a tumbling weight which is employed to work a valve in the fourth compartment, and the tumbling weight is connected to each of the floats, so that supposing either or both of the compartments containing the floats to be full of liquid, the float or floats would be at the top, and as the fluid is drawn from either compartment the float will descend, and its weight acting upon the tumbling weightbefore mentioned, will cause it to fall over, and thereby reverse the position of the valve, and allow the empty compartment to fill with liquid, and the full one can be emptied at pleasure.—Patent abandoned.

2256 J. Roberts, King William-street. Cooling ressels. This consists in constructing, cooling, or refrigerating to be serewed, riveted, or other wast in brass or other material minus the end, namely, that part to which it may be necessary to apply a piece of iron or steel, known to the trade as the shank, being the rend, namely, that part to which it may be necessary to apply a piece of iron or steel, known to the trade as the shank, being the rend, namely, that part to which it may be necessary to apply a piece of iron or steel, known to the trade as the shank, being the rend, namely, that part to which it may be necessary to apply a piece of iron or steel, known to the trade as the shank, being the rend, namely, that part to which it may be necessary to apply a piece of iron or steel, known to the trade as the shank, being the rend, namely, that part to which it may be necessary to apply a piece of iron or steel, known to the trade as the shank, being the rend, namely, that part to which it may be ne

vessels or chambers of perforated metal or other material, in combination with any absorbent substance, by preference French stone or gypsum. This substance is used as a lining, by placing it between two pieces of perforated metal or other material, the shape of which will depend on the purposes for which it is required.—Patent abandoned. doned.

2257 S. DEACON, Hoxton. Sash fastener. Dated July 17,

The fastening consists mainly of two bars or arms work-The fastening consists mainly of two bars or arms working on centres, pins, or pivots. They are toothed at the inner ends, where they engage with each other, and they are worked so that their other ends approach to and recede from each other. One bar is worked by hand, and its teeth engaging in the other bar work it outward or inward as required. When the bars approach and lie near together over the division or opening of the sash, the fastening is effected, the teeth aided by a spring keeping tesbh ar closed.—Patent completed.

2258 R. MELBRUM, Cupar, North Britain. Rasing fuids.

2258 R. MELDRUM, Cupar, North Britain. Rasing fluids.

2258 R. Meldbeum, Cupar, North Britain. Rasing fluidsDated July 17, 1868.

An apparatus is employed divided into chambers, the lower one being a condenser, with a tube in the centre, containing a piston and rod, which is joined to another piston above, and a steam pipe from a boiler with a cock for screwing off and on, so that the steam coming into the chamber below the upper piston lifts the piston up the cylinder, and encloses a valve at a point where there is a tube in communication with a well or source of supply. The upper chamber is the one that the liquid is brought into, and it does not come into contact with the steam chamber. The cylinder at the junctions may be staffed outside to help to prevent rarefaction of the steam in its chamber. When the piston has been driven to the top of the chamber, as described, two rods fixed to the lower piston are raised up with the piston, and a paw with an eye slipping on another rod admits of each of these rods being raised without interrupting anything until the paws come to the connection with the slides of the valves, when they raise these two slides, and also another which closes one steam valve, and opens onother, letting the steam out of the steam chamber into the connection.

doned.

2259 E. A. COWPER, Westminster. Glass ornaments.

Dated July 17, 1868.

This consists in the construction and use of pieces of glass of peculiar form, punched out of a heated sheet or thin piece of glass in such manner that the natural polished surface of the glass is left untouched by the punch or bolster, no hole being formed in the glass so punched out, but the surface on one side being rounded or convex, and on the other side flat, or nearly so. The flat surface can stick on to any article of dress, to be ornamented by means of cement.—Patent abandoned.

2260 D. SOWIEN and R. C. STEPHENSON Bradford. Stufe.

mented by means of cement.—Patent abandoned.

2260 D. Sowden and R. C. Stephenson, Bradford. Shuttles. Dated July 18, 1868.

This invention relates to the pikes of shuttles, and the improvements consist in constructing them with a spring attached at the point and expanding at the root end of the pike. This pike is hinged in the shuttle at the root end (as usual), and a spring peak or stop-piece is fixed, so that when the pike is turned or pushed out from the shuttle to place on or remove the spool therefrom, the spring comes in contact with the plate which presses the spring close against the pike, thereby allowing the spool to pass easily or freely on or off the pike.—Patent abandoned.

2261 D. Werster Southout Gas. Dated July 18.

2261 D. WEBSTER, Southport. Gas. Dated July 18,

1868.

This consists in preventing or removing the accumulation or incrustation of carbonaceous deposit on the interior surface of retorts employed in the manufacture of coal gas, such deposit arising from the back pressure of gas from the "seal dip" in the hydraulic "main." The improvements consist in the employment of a hollow or other ball seated upon a conical seating applied within the ordinary gas exit or "stand pipe," and acting as a valve, such ball being suspended by a chain passing over a pulley or attached to a lever, so that when the gas is rising up the "stand pipe" it will lift the ball valve and pass on, but if the retor the opened for refilling, or other purpose, and the gas ceases to rise its own weight, or the back pressure from the other retorts closes the ball on to the seating and prevents the gas escaping; if desired, an ordinary "clack valve" or other valve may be arranged in the pipe for the same purpose. A supply pipe and exit pipe and taps are also applied to the "hydraulie main," whereby the tar liquor may be drawn off, and the main may be filled with pure water at any moment required. By this means a considerable economy is effected in the manufacture of gas by the prevention of the escape into the open retort by back pressure. The illuminating power is improved and the duration of the retorts is considerably increased by the diminution of the deposit therein, and also the labour of scarfing is prevented.—Patent completed. consists in preventing or removing the accumula-

and also the labour of scaring is prevened.—Fascincompleted.

2262 T. Kendrick and S. Davies, Dudley. Fire-irons.
Dated July 18, 1868.

This consists in casting the head bow and one leg in an entire piece in metal, on the side of the bow, or consignous thereto. There are two projections, by means of which the tongs are extended when the projections are pressed simultaneously. In certain cases, the patentees prefer to cast the head and bow in an entire piece, and attach a leg made with ornamental metal tubing, such leg to be screwed, riveted, or otherwise united to the other parts. The poker may be cast in brass or other material minus the end, namely, that part to which it may be necessary to apply a piece of iron or steel, known to the trade as the shank, being the remotest end from the handle. The head and shank of a shovel is cast in one piece, and the pan is attached to it in the ordinary way. In casting these articles, or portions of the same, it is matter of choice whether they are cast in a solid form or by means of a core to render them partially hollow, so as to economize the weight of metal.—Patent completed.

2263 C. G. JOHNSON, Stockton-on-Tees. Kilns. Dated

partly so, by flues, through which the heated gases from the kilns are led. On the tops of the trucks are clay slabs 2 in. or more in thickness, to protect the metal work of the trucks from the heat of the kiln. According to one arrangement, the bricks or other articles, as they are moulded, are placed on trucks running on rails which pass through a drying flue heated as above described. The trucks enter the drying flue at one end, and when the bricks or other articles are sufficiently dry, the trucks are passed out at the opposite end, the bricks or other articles are then loaded on to other trucks to be burnt. These bricks are carried on trucks running on rails which pass along in front of a series of kilns, so that the trucks upon which the bricks or other articles to be burnt are piled, may be brought in front of any of the series of kilns, and then run off the trucks that carry them on to lines of rails that pass through such flue or kiln, or any other convenient arrangement of points and crossings or turntables may be employed to convey the bricks or other articles from the machine to the drying flue and thence to the kiln or from the machine to the kiln. When a flue or kiln has thus been filled up from end to end with trucks, the kiln is fired through holes in the top, beginning at one end of the kiln and gradually passing on to the opposite end, so as to drive forward the heat, together with the smoke and moisture from the bricks or other articles, and the heated air and smoke is, by means of a chinney, drawn by return flues up the two sides and middle of the drying chamber in which the articles are dried before being burnt. The firing of the kiln baving commenced at one end, is continued by degrees to the other, the amount acted on at one time being regulated by dampers applied to openings from the kiln into the flues.—Patent completed.

2264 J. GUL, Palerno. Engine. Dated Jly 18, 1868.

in which the articles are dried before being burnt. The firing of the kiln baving commenced at one end, is continued by degrees to the other, the amount acted on at one time being regulated by dampers applied to openings from the kiln into the flues.—Patent completed.

2264 J. Gill., Palermo. Engines. Dated July 18, 1868. This consists in improvements in the construction and arrangements of certain parts of the mechanism of heat motive engines. First, in steam engines, and also in engines working by the expansive energy of other hot elastife fluids. The inner surfaces, expassed to the contact of the working steam or other hot fluids, are covered with enamel or glass fused directly on to the metallic surfaces, which are preferably prepared with shallow undercut grooving, or otherwise roughened or furnished with indentations or projections to hold the vitrified coating more tirmly in place; or the surfaces are protected from contact with the working steam by covering them with metallic canefiled plates, or plates of glass, baked earth, or natural stone laid in cement impervious to steam, and held in place by screws, clamps, or equivalent contrivance, instead of mineral covering, as above-mentioned. Second, in steam engines the temperature of the interior rubbing surfaces of the cylinder is kept up for keeping in direct contact with these surfaces as much as possible a movable mass of steam censtantly at or near the full boiler pressure on one side of the piston or pistons while the working steam is undergoing various stages of expansion from full pressure to the vacuum in the condenser on the other side. This is effected by making the cylinder, longer than what is usually required for a given length of stroke, preferably about double that length, and using a long double-headed piston or two pistons firmly connected together. The space being in free communication with the boiler, and preferably forming a passage for the whole working steam on the one hand, and its exhaust into the condenser on the other. Thus the

2265 J. THOMAS, Newcastle-on-Tyne, Smelling furnaces,

2265 J. THOMAS, Newcastic-on-Tyne. Smeating Jurnaces. Dated July 18, 1-865.

The main features of this invention in addition to the general arrangement or combination of the parts, are the construction of water boshes, and the employment of spikes in the water boshes.—Patent completed.

spikes in the water bosnes.—Fatent completed.

2266 W. Berry, Kingsland Green. Lighting shops.

Dat d July 18, 1863.

This consists, first, in making any part of a building, or of any window, movable; the movable portion is supported by guide rods, slides, or other apparatus, and cords attached to the window frame, sash bars, or architectural dressings. Second, at the back of the facia or movable part of a building, an illuminating apparatus is fixed, consisting of one or any number of lights, such lights having suitable reflectors so arranged that the whole or a greater

part of the light may be thrown upon the window; a por-tion of the light may illuminate the facia or other movable part of the building.—Patent completed.

part of the building.—Patent completed.

2267 F. C. Steinbach, Brussels. Pipe joint. Dated
July 18, 1868.

The pipes are formed with a spigot and socket coupling,
and with an annular groove or grooves on the outer
periphery of the one pipe and the inner periphery of the
other, in a manner that will allow (when the pipes are put
together) of the grooves of the pipes to be coupled. Into
the annular chambers molten lead or other metal or plastic
material is run, and, on cooling, a solid locking ring will
be produced.—Patent abandoned.

2268 W. B. Laky, Changer, lang. Peopling. (A com-

be produced.—Patent abandoned.

2268 W. R. Lake, Chancery-lane. Propelling. (A communication). Dated July 18, 1868.

In order to carry out this invention, the patentee employs a case or cylinder provided with a piston, which is brought to act upon the water, by means of a horizontal engine, through a lever with a long and short arm. The piston rod of the engine, by means of a connecting arm, is always connected with the short arm of the lever, which short arm must never exceed one quarter the length of the long arm. A shaft, which forms the fullerum or axis of the lever, may be either supported above, hung below, or placed on the deck of a boat. This shaft may also be provided with a lever for working the valves of the engine.—Patent abandoned.

2269 T. RONELL Newcastle, Slide valves. Dated July 20.

2269 T. BONELL, Newcastle. Stide valres. Dated July 20,

1863.
For this purpose the patentee forms each valve with a solid back, and an outside frame sliding on it and against the central plate, so as to prevent steam passing to the back of the valve. These outside frames are formed with V or wedge-like edges, acted upon by other suitably-formed edges, which are borne upon by springs from the valve.—Patent abandoned.

edges, which are borne upon by springs from the valve,—Patent abandoned.

2270 H. B. Barlow, Manchester. Spinning, &c. (A communication). Dated July 29, 1863.

This invention is applicable to slubbing and roving frames, and other machines for preparing throus substances, and to machines for spinning and doubling. It consists in an improved mode of driving the spindles of such machines, and of arresting the motion of any spindle without interfering with the working of the others. In performing this invention, the spindles to be driven are supported in two bolster rails, and near the lower end of each spindle is fixed a friction pulley made of leather; this pulley rests upon another friction pulley made of east from, fixed on a horizontal shaft, and on this shaft are fixed as many pulleys as there are spindles to be driven. This horizontal shaft is driven, and corresponds to the shaft now in use, when the spindles are driven by bevel wheels and pinions. In front of each spindle, and supported by stude fixed in the bolster rails, is a flat vertical rod, the lower end of which is bent at right angles; this passes under the lower end of the spindle when it is required; to stop a spindle, the attendant slightly raises this rod, and thereby lifts the friction pulley on the spindle out of contact with the pulley on the horizontal shaft.—Patent completed.

this rod, and thereby lifts the friction pulley on the spindle out of contact with the pulley on the horizontal shaft.— Patent completed.

271 T. W. Gray, Limehouse. Lightning conductors. Dated July 20, 1868.

This consists in the application of lightning conductors to ships or vessels of a composite build of wood and iron, and also to ships or vessels of from with wood masts. In the case of a composite built vessel of wood and iron, with wood lower masts, the iron beams, or any iron whereon the line of conductors are fixed, is to be covered with wood or other non-nonducting material, and the plates of metal—or strip of copper, by preference used as lightning conductors—are fixed on the same, or on the under side of wood deck to ship's side, and partly down the ship's side, with metal bolts, in connection through the ship's side, with metal outside, or to the water, more particularly in the case of a double planked or skinned ship's side, so that there may be independent metal bolts for connecting the metal plates or strips with the metal or water outside. In the case of a composite vessel with tabernacle masts, or masts stepping on or terminating at the deck, the same to be fitted—from keel of mast, along upper side of wood deck—to ship's side, and thence overbeard to sea direct. The masts, if of wood, are fitted as usual with plates or strips of metal.—Patent completed.

usual with plates or strips of metal.—Patent completed.

2272 W. WINTER, Leeds. Swing machines. Dated July 20, 1868.

This invention relates to means of working the needles and shuttles of sewing machines, and the improvements consist in the construction and use of self-compensating levers, or levers which compensate for the wear of the joints or connecting parts. Heretofore, in the working of these machines—by the constant reciprocation of the needle bars and shuttle drivers—the joints wear away quickly, requiring frequent repairs. Now, to remedy this evil, the patentee forms the lever arm which connects therewith in two parts or in two prongs, the one having a tendency to spring off from the other. These parts or prongs are (when the levers are applied) pressed together and inserted into a slot hole formed in the needle-bar, and the same with respect to the shuttle-driver, so that, as the slot holes or the levers wear, the expansive tendency of these levers will always compensate.—Patent completed.

2273 W. J. CUNNINGHAM, Oxford-street. Raising blinds.

levers will always compensate.—Patent completed.

2273 W. J. Cunningham, Oxford-street. Raising blinds.

Dated July 20, 1888.

This consists in applying an elastic band or a metal spring to an ordinary nail or hock in the window sash, the other end of which band is sprung on a C-shaped hook round which the cord for raising and lowering the blind works, the hook being hidden from sight by any suitable ornament; or the india-rubber or other band may be sprung on a hook with a pulley attached, around which pulley the cord for raising and lowering the blind runs; so that, on pulling the cord, the blind or other article is raised or lowered without noise and with extreme facility, or a curtain or blind may be pulled aside in a horizontal direction when so required by slightly aftering the position of the respective parts.—Patent completed.

2274 E. Beanes, Maidenhead. Brewing. Dated July 20

2274 E. BEANES, Maidenhead. Brewing. Dated July 20 1868

1868.
This consists in the use of sulphurous acid in the state of gas, or its aqueous solution, or of acid sulphites, or bisulphites of sodium, potassium, calcium, magnesium, ammonium, or aluminium. These chemical agents are applied to the brewing materials—such as malt or sugar—directly, or mixed with the water added to them before their entrance into the mash tun, during the process of mashing, or during the process of boiling the wort with

the hops, but the patentee prefers to operate during the mashing, and with the aqueous solution, or the salts of sulphurous acid. The aqueous solution of acid sulphite of sodium—which will give a slight red colour to blue litmus paper, and a very pule lead colour to red litmus paper, and a very pule lead colour to red litmus paper—is preferred, the proportions being about 16 to 20 ounces of the salt to each quarter of malt, or, when sugar is used for brewing, from about 16 to 20 ounces of the salt to 200lb, weight of sugar.—Patent completed.

brewing, from about 16 to 20 ounces of the salt to 200lb weight of sugar.—Patent completed.

2275 R. SMYTH, Glasgow. Propelling. Dated July 20, 1868. The apparatus comprises a paddiewheel arranged on a vertical shaft in a casing formed in the vessel's sides. The framing of the paddiewheel consists of two discs fixed at right angles on the shaft, and a series of spindles parallel to the shaft extend between, and are carried by them. Each spindle has a pair of short arms fixed on it close to the insides of the discs, and a paddle or float is fitted with journals turning in the ends of the arms so as to turn on an axis parallel to the spindle, such axis being at or near one edge of the float. When the float is pressed in one direction, it bears against the spindle, but when not pressed, it is free to resume the position of least resistance. The positions of the spindles and their arms are, in one modification, controlled by cranks formed or fixed on their outer ends outside of the disc, the pins of the cranks being in holes in a third disc mounted so as to turn on a boss disposed eccentric tily as regards the paddle-wheel shaft, this arrangement being similar to what is in use with ordinary feathering paddle-wheels. The paddle-wheel shaft, this arrangement being similar to what is in use with ordinary feathering paddle-wheels. The paddle-wheel projects partly out of the casing, and as the floats are carried by it out of the casing, they assume positions at right angles to the vessel's course, so as to propel in the most direct and effective manner, whilst, when they are passing round through the interior of the casing, they offer the least possible resistance.—Patent abandoned.

2276 C. P. WILCOX, Mold, Flintshire. Counting machine.

2276 C. P. Wilcox, Mold, Flintshire. Counting machine. Dated July 20, 1568.

This consists of certain elements comprising annull or flanged dises, the flanges being graduated, and the divisional spaces figured or numbered as required, as to form circular or cylindrical scales. These scales are placed side by side on a central shaft, upon which they are free to rotate, and are connected with and turned by each other in succession by wheel work, the whole being enclosed in a cylindrical or other shaped case, having an opening or openings therein through which the figures or numbers on the scale wheels are visible. The central shaft, when turned by a crank or otherwise, gives motion to the first wheel or scale (on the right), the first to the second, the second to the third, and so on, the number of turns of the shaft being indicated by the figures on the rotating scales, from 1 up to 1.000.000 (more or less), according to the mode of gearing and graduating the scales and the number of scales or wheels with which the machine is fitted.—Patent completed.

2277 T. G. GREEN, Derby. Earthenware. Dated July 20

2277 T. G. Green, Deroy. London and the following materials. The patentee takes a material known to minerallogists as granular quartz or taleose quartz, which is a substance containing quartz and steatite or take, and he mixes with this material about two-kixths of China clay and one-sixth of ball clay. The proportions can be varied as circumstances may require. — Patent abandonal

doned.

2278 L. Rose, Leith. Artificial champagne. Dated July 20, 1888.

The patentee first extracts the mucilage from raw lime or lemon juice. This is placed in vats for the mucilage to be thrown down by means of Spanish earth or isinglass. After the juice has become perfectly clear, it is drawn off and mixed with cane or other sugar, using about 6lb (avoirdupois) of sugar to each gallon of juice. This sweetened juice is again refined by subjecting it to the same process. At this period, two per cent, of sulphurous acid, free or combined, as in the form of bisulphate of lime or otherwise, being mixed to prevent fermentation by the action of the sugar on the juice, which being accomplished, the juice is drawn off into champagne bottles, filling the bottles half full with this syrup, and afterwards it is acrated by any suitable process, such, for instance, as the process adopted in making lemonade.—Patent completed.

2279 R. Brett and G. Danielles, Bentley, Suffolk. Farm

aerated by any suitable process, such, for instance, as the process adopted in making lemonade.—Patent completed, 2279 R. Brett and G. Danielle, Bentley, Suffolk. Farm machinery. Dated July 20, 1868.

This consists of improvements in engines to be chiefly employed in ploughing land. The patentees mount the drum upon a shaft, which is supported at top in the frame of the machine, but free to oscillate thereon; the shaft passes through the drum, and its position is regulated by a set screw working in a frame below, so that by turning the serve with drum may be set at any angle that may be desired for the efficient working thereof, viz., for winding thereon the wire or other rope to haul a plough or other implement. The drum is driven from the crank shaft of the engine, to which a bevel pinion in keyed, in gear with another and similar bevel pinion on a horizontal shaft carrying another pinion is capable of being allowed to run loose on the shaft when it is not required to drive the drum. Sometimes, instead of using the bevel pinions before described, motion is imparted to the horizontal shaft by a strap or straps from the crank shaft of tengine. Another part of the invention relates to appartus for moving the machine from place to place, along the headland, for example. It consists of a drum or wheel to receive a wire or other rope on each or either end thereof; the drum, which may be made in one or several parts, is fitted with cogs or teeth, and motion is imparted to it by a worn on the horizontal shaft of the machine; a clutch is provided for throwing the worm in or out of gear with the teeth on the drum, according to whether it is desired to drive the drum or to allow it to remain at rest.—Patent completed. to drive the drum or to allow it to remain at rest, -Patent completed.

J. RAINE, Richmond, Yorkshire, Photography.

Dated July 20, 1868.
This consists in dividing the camera into two or more equal This consists in dividing the camera into two or more equal parts by means of a division so constructed as to produce a picture with a soft or vignetted margin, and an arrangement by means of which the camera, after one view has been obtained, may be moved through such a degree of space as to cause the margin of the second picture taken so to superimpose and unite with that of the first as to yield a panoramic view by the junction of the several pictures thus obtained. The method employed to effect this softening of the margin consists in having a divisional partition in the camera, which division is composed of a

metal or other band with serrated edges, and passing metal or other band with serrated edges, and passing over two pulleys—one at the top and the other at the bottom of the camera. The width of this band is so adjusted that when a lens is fitted into each division of the camera, and a sensitive plate is exposed when the camera is pointed at any uniform body, the serrated edge of the band — which must be moved by means of a handle attached to the axis of one of the pulleys over which it travels—shall so soften the edges of each picture as to produce a continuous effect of lighting. To apply this for taking a penorama, the camera is made to rotate upon a table in such a manner that, after a view has been taken on one portion of the plate by means of one lens, the camera is rotated a certain previously determined distance, and the second picture is taken.—Patent abandoned.

2281 J. Hodeson, Richmond, Surrey. Transporting

on one portion of the plate by means of one lens, the camera is rotated a certain previously determined distance, and the second picture is taken.—Patent abandoned.

2281 J. Hodden, Richmond, Surrey. Transporting loads. Dated July 20, 1868.

This relates to transporting produce or material, contained in a suitable vessel or carriage, along a rope or wire stretched between two fixed points; and the improvements consist in so arranging the supporting points of such rope or wire, and so constructing the pulleys, sheaves, or wheels and pendants which suspend the vessel or carriage, that the pulleys shall be capable of passing the supporting points of the rope or wire without hindrance, thus enabling the wire to be supported at any required number of points, and thus establishing a continuous communication for any desired distance, and also in combining, with the employment of a pair of fixed wires or ropes placed side by side, the use, as herein described, of a continuous endless rope or wire passing round pulleys or sheaves placed near the extremities of the fixed wires or ropes, and capable of receiving motion from the revolution of these palleys or sheaves, which revolution is to be caused by the application to them of any suitable power. By this means the distribution of the material (to be carried in suitable vessels or carriages) is secured at stated intervals along the line of carrying wire or rope, so that no portion of the wire shall be unduly weighted, but that a continuous stream of vessels or carriages shall be constantly transmitted in one direction on one wire, and in the opposite direction on the other for such distances as shall be required. In mounting the wires for this method of continuous transmission, it is proposel to secure them on each extremity of a cross bar of any convenient length, fixed to a post or other upright of such height as circumstances shall require, and hold them in a loop of iron fixed to the extremity of the cross bar, or pass them through a channel similarly fixed, the side

completed.

2282 W. H. and A. M. BATES, and H. FAULKNER, Leicester. Flexible tube. Dated July 20, 1868.

The patentees make use of a core of india-rubber, which is capable of being stretched or extended longitudinally, so that, by reducing its diameter, it may be more easily withdrawn from the interior of the tube, when the latter is finished, than the cores now employed in the manufacture of tubular articles. Upon a core thus made, a tube is formed in the ordinary way, either of sheet rubber, or of compland, or of rubber cloth, and this constitutes the lining of the improved tube or hose. The covered core is then placed in a braiding machine supplied with any suitable number of threads or wires according to the intended diameter of the tube; and these threads are braided round the core in the well known manner, but very tightly. The core, as it travels forward to the braiding threads, must be coated or payed over with solution in which the braiding threads will imbed themselves as the braiding operation proceeds.—Patent completed.

2283 A. HOMFRAY, Worcester. Screening and washing

threads will imbed themselves as the braiding operation proceeds.—Patent comploted.

2283 A. Honfray, Worcester. Screening and washing coal. Dated July 20, 1868.

This relates to an improved means of separating the coal from bats. An inclined screen or platform is constructed, the surface of which is divided. The lower edge of each portion into which the screen is thus fivided is situated somewhat higher than the top edge of the portion next below it. The screen is thus made to have a step-like figure. Between the bottom edge of one step and the top edge of the next below it, an open space is left of sufficient width to let the bats and other impurities fail through. The coal to be treated is put on the top of the screen, which is set at such an angle that the coal descends thereon. The pieces of coal acquire in descending such a momentum that they are carried on to the top of the second step. The bats being flat and specifically he vier than the coal, there is greater friction between them and the screen, and on reaching the edge of the first step they fall through the opening there, and are thus separated from the coal. When the bats approximate in density and size to the lumps of coal, a transverse bar is fitted to the second step, which arrests the motion of any bats that may not have fallen through the opening and prevents them acquiring sufficient momentum to carry them over the opening at the bottom of the second step on to the third step. Any required number of steps with openings in the screen, in order to separate any coal that may adhere to or have fallen through them.—Patent completed.

2284 C. Weekes, Westminster. Fortifications. Dated July 20, 1868.

2284 C. WEEKES, Westminster. Fortifications. Dated

The patentee proposes to make rectangular shells of three kinds—lirst, an iron brick of the length, width, and depth of a common brick; second, an iron quoin or angle brick, being by preference of the length of a brick and a-half along each outer face, the width and depth being as before stated; the third, a T or iron tie-brick, the length, width, and depth of each limb being also equal to that of a common brick. The whole of these shells or iron bricks, quoins, and ties are intended to take the place of ordinary bricks in any kind of structure. These shells may also be formed so as to dovetail or lock into each other by projections on one brick fitting into recesses in the other.

The joints may be close or surface joints, made with iron or other cement, or run with lead or other metal or materials. The angle bricks or iron quoins to be applied to all main wall or other angles, and the Ts or tieblocks to all junctions of cross walls with main walls.—Patent completed.

waii or other angles, and the Ts or teblocks to all junctions of cross walls with main walls.—Patent completed.

2285 F. Green, Fulham. Lamps. Dated July 21, 1863. For this purpose a long closed receptacle or vessel is constructed, fixed by preference in the back of a carriage, into which vessel the volatile oil or spirit is introduced through the roof of a railway carriage. At each end of the vessel an overflow pipe is fixed therety, leading down to an overflow reservoir situated und smeath the carriage or seat so that, should the vessel be fixed beyond the desired level, or should it be tilted considerably by the motion of the carriage, the oil or spirit will escape through such overflow pipes, and be collected in the overflow reservoir. On the upper surface of the vessel are fixed one or more burners, through which the vapours of oil or spirit rise, and are burnt; just below the top of the burner is fixed a cup or receptacle, into which a small quantity of spirit is poured when it is desired to light the lamp, which spirit, in being ignited, heats the burner sufficiently to volatilize the oil or spirit in the wick that passes partially up the burner, and thus the lighting of the lamp is readily effected.—Patent abandoned.

2286 T. KOHN, Hartford, U.S.A. Cleaning silk. Dated

lamp is readily effected.—Patent abandoned.

2286 T. KOHN, Hartford, U.S.A. Cleaning silk. Dated
July 21, 1868.

The object of this is to lessen the breaking of threads
during twisting, and consists in taking the threads from
the bobbins, leading them up and down, over and through
guides, and into a vat or trough containing liquid, thence
on to the reels.—Patent completed.

2287 T. DESCHAMPS, Paris. Glore fastener. Dated July 21

This consists in the combination of a hooked plate a short piece of braid or tape on one side of the glove, and an eyelet on the other. The plate is adjustable on the braid. Also in the use of a loose ring on the tape to pass over a stud.—Patent completed.

over a stud.—Patent completed.

2238 F. Warren, Birmingham, Heating water. Dated July 21, 1868.

This consists, first, of a hollow ring, which forms the base of the apparatus, in which ring an opening is made for the inward flow of the water. This ring is fitted with any number of tubes, so arranged as that they shall converge into a centre, and connect with another ring or chamber above. In the upper ring or chamber an opening is made for the outlet or flow of the heated water through a tube attached thereto. Second, a stove or casing of metal is constructed and lined with fire bricks or other suitable material. A space is left where necess try between the one which constitutes the fire chamber. This chamber is made sufficiently large to allow of the boiler or heater being suspended or fixed therein.—Patent abandoned.

2259 A. A. Wille, Woodford, Beaching feathers. Dated

2289 A. A. WILLE, Woodford. Bleaching feathers. Dated

The feathers are first washed and fatty particles removed therefrom, after which they are steeped in a bath, composed of water, muriatic acid, and chromate of potash, sulposed of water, muriatic acid, and chromate of potash, sulphate of copper, and sesquioxide of iron, the proportions of these ingredients being for a bath, for, say, 2th avoirdupois of feathers, 12 gallons of water, 14 pint of muriatic acid, 5 oz. of chromate of potash, loz. of sulphate of copper, and 1-8th pint of fluid sesquioxide of iron. This bath is heated to a lukewarm temperature, and the feathers are allowed to remain in the same for about three days, more or less, depending upon the quality of the teathers. These are then removed and washed with soap, and rinsed, after which they are to be steeped first in a boiling solution of salt of sorrel, and lastly ina cold bath composed of starchy water, with a small admixture of blue and pink colouring matter. The feathers are then dried and well beaten, when they will be ready to be curled and otherwise prepared for use.—Patent abandoned.

2290 J. M. HECTOR, Dorset. Pusee boxes. Dated July 17.

2290 J. M. HECTOR, Dorset. Fusee boxes. Dated July 17,

2290 J. M. HECTOR, Dorset. Pusce boxes. Dated July 17, 1868.

The boxes are formed with a sliding or opening side, which, when opened, allows the inner mechanism to be adjusted, and the box to be supplied with fusces. It also has a sliding or opening end, which, when pushed aside, allows the fusce to protrude from the box in obedience to the action of the mechanism. At one end of the box is pivoted a hollow drum, provided with a coil spring, and to this drum is attached a cord, which passes round a pulley at the opposite end of the box, and is then attached to a cross bar, which can slide up and down the box in slots or guides provided for the purpose. When the box is to be filled, the sliding or opening side is removed, and the cross bar is drawn to the end of the box, and there held by a catch or other suitable contrivance. The fusces are then laid in the box with the heads and splints alternately pointing to each side, the ends of the splints being inserted into the slots, until a layer of fusces is placed from the crosspices above mentioned, to the sliding or opening end of the box. Then the sliding or opening side is closed, the eatch being at the same time released. The spring in the drum, which is now coiled, acts on the drum and puts a tension on the cord tending to draw the cross bar to the end of the box and pushing the fusces before it.—Patent completed.

2291 J. J. ASTON, Temple. Propelling. Dated July 21,

1868. This relates to an improvement to the floats. The inner ends of the floats nearest to the boat are curved, and so formed as not to work close up to the vessel, like the ordinary floats. One effect of the improved floats is that the water is not forced too much against the sides of the vessel, as by the ordinary floats, the speed of the vessel is thereby accelerated. Another effect is that the vessel will be less shaken, as the floats enter into and leave the water more gradually than the common floats.—Patent abandoned.

2992 A. M. CLARK, Chancery-lane. Feeding boilers, (A communication). Dated July 21, 1868.

This consists of a self-feeding apparatus. A float is employed, maintained on the surface of the water; the float is an connection with a bell crank lever to the stem of a valve placed within a connection piece of the suction pipe. When the float descends to the lowest level, the valvo is opened, and water is free to pass the piston of the pump, which is kept always in action.—Patent completed.

2293 T. Gibb, Jarrow-on-Tyne. Treating ores. Dated July 22, 1868.
In treating ores or compounds containing sulphides, the patentee employs, for the purposes of calcination, a furnace

of any form, having one end thereof maintained at a conof any form, having one end thereof maintained at a considerably higher temperature than the other end. The re-containing sulphur, as before mentioned, is placed on the hotter part of the bed near the fire bridge, and there calcined until the sulphur is expelled, or until the ore is, as it is technically termed, "dead." It is then moved towards the flue or cooler end of the furnace, and a fresh charge of ore placed on the hot bed. The gases produced in calcining the freshly charged ore pass over that previously charged, and change the oxides of copper or other metal contained in the latter into sulphate; should this effect not be completely obtained by the sulphurous acid gas produced in calcining the ore, sulphurous acid gas otherwise produced may be passed through the furnace.—Patent completed.

2224 4 Markin Stroud. Edition. Dated July 22, 1868.

Patent completed.

2204 G. Martin, Strout. Fabrics. Dated July 22, 1868. The rags or materials to be operated upon are placed in a suitable stove or chamber. The vessel or chamber is then made as air-tight as is practicable, and a vacuum or partial vacuum created therein by exhausting the air therefrom as completely as possible, as well understood. In connection with this vessel or chamber is placed a generator of any suitable and convenient form, in which is generated the gas, vapour, or steam necessary for the operation. The gas, vapour, or steam is allowed to enter the vessel or chamber by pipes, such vessel or chamber being previously heated to bodge, or 200deg. Fah. For bleaching purposes, a sulphur stove or retort is connected with the vessel or chamber, and charged with sulphur vapour. The rags or other materials having been subjected to the influence of the sulphur vapour, are then washed and prepared in the usual manner.—Patent completed.

2205 C. W. Bradshaw, Stubbington, Hants. Coupling

and prepared in the usual manner.—Patent completed.
2295 C. W. Bradshaw. Stubbington, Hants. Coupling
pipes. Dated July 22, 1868.
This consists in the employment of a male and female
socket so arranged that a ring is introduced between the
two before joining, upon which ring eccentric grooves are
formed which act upon two wedge-like pieces of metal
introduced in openings formed in the female socket. By
turning the ring before mentioned the wedges are drawn
in and close upon a bevel in the male socket, and thus
form a secure and water-tight joint.—Patent abandoned.

in and close upon a bevel in the male socket, and thus form a secure and water-tight joint.—Patent abandoned.

2266 J. H. Johnson, Lincoln's Inn-fields. Colouring matters. (A communication). Dated July 22, 1868.

This relates to the production of a red colouring matter from and by means of a substance or produce derived from maphthaline by means of nitric acid, and after the separation of the free acid from the nitro-naphthaline. The product thus resulting is subjected to the reducing action of either zine or iron or other reducing agent in conjunction with an acid, by preference acetic acid. The product thus obtained is then to be acted upon at a temperature of about 120 deg. Centigrade, with acetic acid, by preference crystallizable, and with a nitrate, by preference nitrate of soda, and to this mixture, or to the substance thus acted upon, naphthalamine is added; the mixture is allowed to remain at or about the temperature indicated, until the desired colour has been produced; it is then removed, and after being subjected to the action of cold water and hot water, containing acetic acid, the colouring matter is obtained in solution, from which it may be separated either by means of common salt or otherwise, as is well understood by manufacturers of aniline colours. The colouring matter thus obtained may be dissolved in alcohol or other solvent, and may be employed for the purposes of dycing and printing.—Patent completed.

2297 S. LANGDALE, Newcastle. Artificial manures. Dated July 22, 1868.

This consists in subjecting mineral phosphates of limo or coprolites in a divided condition to the action of sulphuric acid at or about its boiling point the decomposition of the phosphate will be much facilitated, and the solution of certain compounds of iron which may 16 present will be prevented or diminished.—Patent abandoned.

# APPLICATIONS FOR LETTERS PATENT.

Dated January 26, 1869

236 C. L. Wood, Howlish Hall, Bishop Auckland, Durham, and J. Stockley, Newcastle-on-Tyne, Northumber-land, Improvements in apparatus for grinding plate glass.

237 E. D. Ruston and W. W. Mills, Birmingham. Improvements in supporting and flying win-low sashes, which improvements are also applicable to the supporting and flying of the windows of railway and other carriages and suspended doors and shutters.

238 J. D. Ellis, Sheffield. An improved method of rolling armour plates.

ing armour plates.
239 J. and J. Wilson, and G. Cryer, Cross Hills, Kild-wick, Yorkshire. Improvements in machinery for preparing, drawing, and finishing wool, cotton, and other

ores. 240 J. Millar, Cambridge-road, Middlesex. Improve-

240 J. Millar, Cambridge-road, Middiosex. Improvements in the manufacture of envelopes.

241 J. Wilson, Poppleton, Yorkshire. Improvements in machinery for shaking straw.

242 J. Pickering. Glasgow. Improvements in treating timber, and in the means employed therefor.

243 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in ventilating apparatus. (A communication).

243 W. R. Lake, Southampton-anisings, Chancery-lane. Improvements in ventilating apparatus. (A communication).

244 A. V. Newton, Chancery-lane. Improvements in machinery for cutting veneers. (A communication).

245 H. Law, Essex-street, Strand. Improvements in apparatus for connecting soft metal and other pipes, and for attaching cocks and other fittings thereto.

246 C. Gill, Boulevart des Capucines, Paris. Improvements in the manufacture of sugar.

247 C. French, Omega-terrace, Eandford-square, Middlesex. Improvements in means or apparatus for intercommunication on railway trains.

248 C. Marher, Salford, Lanca-hire. Improvements in machinery or apparatus for singeing fabries by gas flames, 249 T. Reeder, Preston, Lanca-hire. Improvements in the manufacture of sheet metal rolers, and in the machinery employed therein.

250 J. Gough, Kirby-street, Hatton-garden, Middlesex, Improvements in applying ink or colour to printing surfaces.

fac

ares. 251 J. Taylor, Britannia Works, Birkenhead, Chester

Improvements in machinery or apparatus for propelling ships, also partly applicable as hoisting tackle and for other purposes.
252 T. Vaughan, Middlesborough-on-Tees, and J. W. Smith, Manchester. Improvements in treating smoke and soot for the preparation of an article of commerce therefore.

therefrom.

253 H. Barcroft, Glen, near Newry, Armagh, Ireland.
Improvements in the manufacture of damasks and other
similar material, and in the machinery therefor.

254 J. Porteous, Edinburgh, and H. Gibson, Musselburgh, Mid Lothian. Improvements in the manufacture
of tobacco, and in the machinery or apparatus employed
therefore.

of tobacco, and in the machinery or apparatus employed therefor.

255 T. Brown, Newgate-street, City. Improvements in liquid discharging apparatus for extinguishing fire and other purposes, and in the means for generating gas within such apparatus. (A communication).

256 J. H. Johnson, Lincoln's Inn-fields. Improvements in keys or wedges to be employed in the permanent way of railways, and for other like purposes. (A communication).

257 B. Girdwood, Edinburgh, Mid Lothian. Improvements in envelopes, and in bags such as are used for transmitting samples.

238 E. H. Prentice, Stowmarket, Suffolk. Improvements in the manufacture of phosphatic manures.

ments in the manufacture of phosphatic manures.

259 J. Silman, Birmingham. Improvements in the manufacture of knives for cutting out the soles of boots and shoes.

G. Tangye, Birmingham. Improvements in letter

copying presses.

261 C. Lungley, Greenwich, Kent. Improvements in letter
building and working caiseons and pontoons for lifts and
floating and dry docks and other structures in iron and

floating and dry docks and other structures in iron and wood.

262 A. C. Pass, Bedminster Smelting Works, Bedminster, Bristol. Improvements in the method of, and apparatus for, condensing and purifying metallic and other rumes, vapours, gases, and smoke, and in obtaining oxide of zinc.

263 C. W. Petersen, Norton Folgate, City. Improvements in lifeboats, which improvements are also applicable to steam tags, pilot-boats, and tenders.

Dated January 28, 1869.

264 R. M. Marchant, Torrington-square, Middleeex. An improved mode of obtaining and applying power for locomotive and stationary purposes, and apparatus connected therewith.

265 W. Sourrier. Birmingham. An improvement in

nected therewith.

265 W. Spurrier, Birmingham. An improvement in salt spoons and other spoons.

266 W. Brown and T. H. Garbutt, Seamur, near Scarborough, Yorkshire. Improvements in firebars.

267 R. Jones, Botolph-lane, City. Improvements in means or apparatus used in curing or preserving animal substances, which improvements are also applicable in cleansing and impregnating vegetable substances.

268 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in machinery or apparatus for washing

Improvements in machinery or apparatus for washin wincing, fulling, and finishing textile fabrics. (A com

munication).
269 C. L. A. Hoelscher, Fleet-street, City. A musical

chair or seat.
270 B. Blackbee, Norfolk-road, Dalston, Middles

chair or seat.

270 B. Blackbee, Norfolk-road, Dalston, Middlesex.
An improved pessary.

271 A. Browne, King William-street, City. An improved rotary engine. (A communication).

272 L. P. Hebert and L. A. Moulin, Neulily-on-Seine, Arenue due Roule, Department de la Seine, France. An improved press for stamping letters, books, and documents with ink or other colouring matter.

273 J. Box, South Sea House, City. The destruction of burrs or other vegetable or ligneous matters found in wool in its raw or ummanufactured state.

Dated January 29, 1869.

274 J. Easterbrook, J. H. Allcard, and A. M. Wild, Sheffield. Improvements in apparatus for grinding and polishing engine slide bars, shear blades, marble slabs, saw blades, and other flat surfaces where great accuracy is required.

275 N. C. Szerelmey, Belgrave-road, Pimlico. Improvements in making tarpauling in different colours, and in treating sail cloth and other fabrics to preserve them from rapid destruction by the sea, air, and other corroding influences.

276 G. Hawkeley, Montrose Villas, Caledonian-road, Middleser, Improvements in Middleser, Improvements Improvements in Middleser, Improvements Im

rapid destruction by the sea, air, and other corroding influences.

276 G. Hawksley, Montrose Villas, Caledonian-road, Middlesex. Improvements in the manufacture of ventilators and chimney-pots.

277 W. M'Lean, Glasgow. Improvements in printing, and in the machinery or apparatus employed therefor.

278 J. Pickering, Glasgow. Improvements in the propulsion of ships, vessels, and boats.

279 T. W. Carter, Gray's Inn-road, Middlesex. Improvements in the construction of ships and vessels, in order to facilitate propulsion and steering, and the protection and repair of the propellers and rudders.

280 J. M'Donaid, Hackney, Middlesex. Improvements in stoppers or valves for bottles and other like vessels.

281 S. Smith, Hyson Green Brass Works, near Nottlingham. Improvements in tape or valves for regulating the flow of steam, water, and other fluids.

282 G. Hawksley, Montrose Villas, Caledonian-road, Middlesex. Improvements in pumps, and in apparatus connected therewith.

283 G. Price, Birmingham. Improvements in window fastenings.

283 G. Price, Diffininguals.
fastenings.
284 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of piles, faggots, or billets of iron or stoel, and in the machinery or apparatus employed therein. (A communication).
285 A. M. Clark, Chancery-lane. Improvements in machinery for hulling or decorticating grain. (A communication).

nication).

286 A. Mallard, Moorgate-street, City. Improvements in horse shoes. (A communication).

287 F. Jay, South Lambeth-road, London. Improvements in the manufacture of oil paint.

Dated January 30, 1869.

288 T. E. Lundy and T. Hood, City-road, Middlesex. Improvements in apparatus for driving sewing machines by electro-magnetism.

289 T. Whimster, Perth, North Britain. Improvements in apparatus for exhausting, washing, and forcing

by electro-magnetism.

289 T. Whimster, Perth, North Britain. Improvements in apparatus for exhausting, washing, and forcing gaseous or seriform bodies.

290 P. J. Wielemans, Lisle-street, Leicester-square, Middlesex. Improvements in ovens.

291 W. Weldon, Park Villa, West Hill, Highgate, Middlesex. Improvements in the regeneration of certain compounds of manganese from certain residues, and in the manufacture of chlorine and oxygen.

292 T. Pimbley, Bayham-street, Camden Town, N.W. An alarm communication between railway passengers, guard, and engine driver.
293 S. Taylor, Sheffield, and G. W. Dyson, Tinsley, Yorkshire. Improvements in the manufacture of spade and shovel moulds.
294 H. N. Nissen, Mark-lane, City. Improvements in printing bankers' cheques and similar documents.
295 K. C. Watson, Glasgow, Improvements in boats.
296 E. T. Hughes, Chancery-lane. A new file planing machine. (A communication).
297 E. T. Hughes, Chancery-lane. A new file cutting machine. (A communication).
298 R. Wood, Sowerby Bridge, near Halifax, Yorkshire. Improvements in steam engines, or applicable thereto.
299 J. Tolson, Dalton, near Huddersfield, Yorkshire. Improved means or apparatus for cleaning the eards of carding engines or machines having cylinders or rollers clothed with cards used in the preparation of wool, cotton, or other fibrous substances.

or other fibrous substances.

300 G. H. Adam, Birmingham. New or improved apparatus to enable the driver of a locomotive engine to ascertain the condition of the train drawn by the said engine.

301 T. H. Kilner, Lepton, near Huddersfield, Yorkshire. An improved feed apparatus adapted to carding and condensing machinery.

densing machinery.

302 Å. S. Andrews, James-atreet, Old-street, Middlesex.

densing machinery.

302 A. S. Andrews, James-street, Old-street, Middlesex. Improvements in horse collars.

Dated February 1, 1869.

303 J. T. Bintley, Kendsl, Westmoreland. Improvements in billiard tables and bagatelle tables, by which balls may be sent or returned to either end thereof otherwise than along the surface.

304 J. Whyts, Hoxton, Middlesex. Improvements in the construction of tallors shears and scissors.

305 C. D. Abel, Southampton-buildings, Chancerylane. Improved modes of, and apparatus for, casting ingots. (A communication).

306 T. G. Daw, Regent-street. An improved machine for forming stereotype matrices.

307 J. A. Limbert, Gravesend, Kent. Improvements in machinery or apparatus for raising, lowering, and moving heavy bodies, and for operating punching machines and the feed motion of circular and other saws.

308 J. A. V. Newton, Chancery-lane. Improvements in machinery for condensing alivers. (A communication).

309 J. A. A. Fontaine, Somerset Hotel, Strand. An improved hydrostatic hoist.

# NOTICES OF INTENTION TO PROCEED WITH PATENTS. From the "London Gazette," February 2, 1869.

From the "London Gasetta," February 2, 1889.

2906 J. G. Piton. Bushing the sheaves of blocks employed for lifting heavy weights.

2918 F. C. Caivert. Dyeing yarns.

LONDON: FRIDAY, FEBRUARY 12, 1869.

# SMITH'S LIQUID FUEL FURNACE.

THE important question of raising steam by means of liquid fuel appears to find a more ready solution on land than it does on We have several examples of the successful application of the principle to land boilers, but only one instance, at present, on a practical scale, of its adaptation to marine boilers. This arises, to some extent, from the different conditions of each case, the facilities being far greater in many respects in a factory than on shipboard. It is, however, we believe, only a question of time to over-come these difficulties, and to render the adoption of liquid fuel afloat as simple and as easy a matter as it now is ashore. But in the meantime, we are carefully noting its progress on terra firma, and to this end we recently visited the works of Mr. A. Smith, at the Marsh Gate, Stratford. Mr. Smith is a large manufacturer of brushes, which are made from the fibre of the cocoa-nut shell, and in his factory is a considerable quantity of machinery. This, of course, involves the use of steam and the consumption of coal to raise it. Now, coal—as all steam users know is an expensive item in the year's accounts, and an opportunity offering of using creosote, Mr. Smith devised a method of burning it with highly satisfactory results. But before success was achieved, some twenty different modifications of the system were tried, until at length—about a year ago—the present arrangement was finally decided upon, and has been at work ever since. The apparatus is as simple as it well can be, consisting only of a supply tube for the creosote and a steam jetinside it. The creosote is stored in an underground tank outside the engine-house, from which it is forced up by steam pressure into a reservoir, also outside the engine-house, and to which is attached a float and a graduated scale, by which the consumption of oil is ascertained. A supply pipe from the cistern with a regulating cock is turned into the tube of each of two Cornish boilers, 18ft. long, 5ft. diameter, with flues 2ft. 6in. in diameter. The oil supply pipe projects about 9in. into the boiler tube, the mouth of which is simply covered by a plate of thin sheet iron, which is raised or lowered to regulate the draft. Into the oil tube is turned a smaller tube carrying the superheated steam, which issues from small apertures at its nozzle.

The creosote is thus driven into the furnace with great force, being broken up into the finest spray, and forming a powerful flame, which impinges upon a heap of brick core in the tube which is maintained at a red heat.

From the single jet, steam is easily kept in each of these boilers at a constant pressure of from 55lb. to 60lb., which is supplied to or from 5515. to 6015, which is supplied to two engines for driving the machinery. One of these engines is a 10-horse power horizontal; the other, a 30-horse power beam engine. Besides the two boilers already mentioned, there is a third of the same dimensioned, in which steam is kept up by the waste and refuse produced in the factory, the steam being used only for heating purposes, and not for the engines. This boiler is always going, and in the morning supplies steam with which the creosote furnaces are started. From what has been stated, it will be readily

and his consumption for the two boilers is seven barrels of thirty-six gallons each per day of 12 hours. But taking the cost at the fair price of 1d. per gallon, we have only £1 1s. per day, or 10s. 6d. for each boiler. Mr. Smith's consumption of coal used to be 21 tons per day—a great contrast in point of expense to his present working. Then, there is a further saving in attendance, a boy being well able to do all that is necessary, whilst there is no clinkering, nor are there any firebars to burn out. Altogether, a great economy is realized, and much credit is due to Mr. Smith for the simplicity and efficiency of his invention, which he has patented.

Before concluding, it may be interesting to notice the leading features of the conversion of the shell or husk of the cocoa-nut into fibre, for the various purposes to which it is now applied. The shell or outer covering of the nut is first soaked in a tank of water kept warm by steam from the third boiler we have noticed. When sufficiently soaked, the shells are conveyed to a hopper, through which they are fed to a crushing mill. This mill consists of two coarsely-fluted rollers, between which the shells pass and are crushed. They are They are removed thence to the fibre mills, of which there are fourteen. Here the shells are drawn in between two rollers, behind which are arrangements for tearing away the finer fibre and leaving the coarser in the hands of the operator, who presents first one and then the other half of the shell to the action of the mill. The coarse fibre is then carried away and prepared for conversion into brushes and brooms. There are twenty boring lathes in another part of the factory, at which as many men were at work boring the holes in the heads and backs of future brooms and brushes which are to receive the tufts of prepared fibre. The finer portions of the fibre are removed from the mill, and undergo a process of final dressing. This is effected by feeding them through a hopper into a circular screen in which an Archimedean screw rapidly revolves. The fine fibre is delivered at the mouth of the screen, whilst the dust and smaller particles of fibre are carried through the sieve. The fibre thus produced is used for making mats and matting; the siftings find a ready sale with florists and market gardeners for manure. As the sweepings and refuse are collected and burned under one of the boilers, it will thus be seen that every particle of the husk of the cocoa-nut is utilized in a manner beneficial to the interests of mankind.

## THE CHALMERS TARGET.

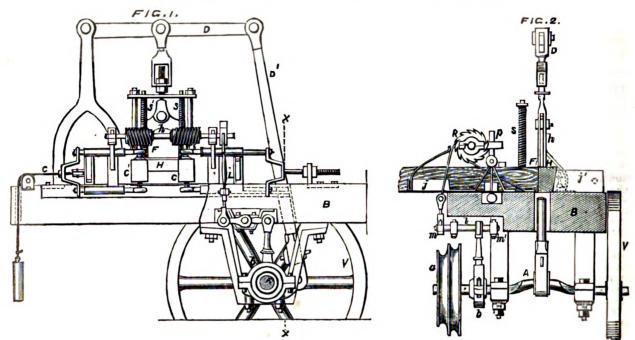

THE recent death of Mr. James Chalmers lent a melancholy interest to the experiments which were carried out at Shoeburyness yesterday week with the last target designed by that gentleman. Although considerable hopes were entertained of the new target, they were not realized on the present occasion, the target having been pierced in every direction with the projectiles which were directed against it. Our readers are so well acquainted with the details of the Chalmers target, that it is unnecessary here to repeat them. It will be sufficient to state that the target lately experimented on was 15ft. long, by 9ft. high, the face being composed of two 4½-inch armour plates of the same length as the target and 4ft. 6in. deep. The target was 2ft. 94in. thick including the angle iron ribs at the back. Mr. Chalmers had introduced eight modifications of backing, so that the target was divisible into as many different parts, each representing a mo-dification of the general principle. A "Warrior" target had been made, and was placed

Chalmers target, it is unnecessary to follow closely the details of firing. Eight rounds in all were fired, five with solid shot and three with live shell. Rounds 1, 4, and 5 with solid shot were directed against the "Warrior" target, through which they failed to pass. Round 1 knocked a piece out of the edge of the target, and rounds 4 and 5 penetrated the target, but remained in it. Rounds 2 and 3 with solid shot were fired at the Chalmers target, through which they passed clean out to the rear. The first live shell struck the to the rear. The first live shell struck the "Warrior" target, making a hole 22.3 inches deep, whilst the second and third shells passed through the Chalmers target, and burst in the rear. It was thus made apparent that the face plate of the latter target was much too weak for the work it was designed to do, and that in effect Mr. Chalmers had pushed his principle of elasticity too far. There is no question of the soundness of the principle, but the extreme lightness of the outer plate neutralized any effect obtainable from the backing. It is to be regretted that such a mistake in the designs of this target should have been made, and still more that the inventor is not here to profit by it, and to bring the labour of years to a successful iggne.

# THE SANITARY CONDITION OF OUR NAVY.

THE sanitary condition of the British Navy is a matter to which considerable interest has always attached, and which has been increased of late years by the introduction of iron-clad ships. It was one of the arguments against them that, under certain conditions, disease would be engendered, and that health in general would suffer. perience has proved that not only is this not the case, but that iron-clads show very favourably as to their general sanitary condition when compared with other vessels. The comparative freedom from disease in iron ships is strikingly evidenced in the reports which have passed through Dr. Mackay's hands, and which are embodied in the blue book just issued, relative to the health of the navy for the year ending June 30, 1868. The average ratio of cases of disease and injury in our iron-clads appears to have been 1340.8 as compared with 2065.8 in the second-rate vessels; 1459 in fourth-rate, 1457.1 in fifth-rate, 1541 in sixth-rate, 1940.4 in sloops, 2227.7 in gun vessels, per 1,000 of force. On the home station the iron-clads were the healthiest of "Warrior," "Defence," "Royal Oak," and "Pallas," exhibit the highest ratio of cases in the sick list. In the "Warrior," catarrh prevailed, but no serious disease occurred. The "Defence" was a newly-commissioned ship, and only trifling ailments attacked her crew. The men of the "Royal Oak" suffered less than might have been expected from "enthetic" disease, which was also of a less severe type. This is attributed to the a less severe type. This is attributed to the fact that the Contagious Diseases Act is in operation at Portsmouth, where the men went on shore. The same ship went to Portland, and at that time the men contracted more disease on shore, and it was of severer type, the Act not being in opera-tion at Portland. On board the "Pallas" mumps occurred. So that in the iron-clads on the home station the sickness was not of a severe kind. A large amount of the sickness on board the iron-clads in the Mediterranean was of a trifling nature. The "Lord Warden" shows the highest ratio of cases, almost entirely attributable to the prevalence of catarrh. So with the "Caledonia." understood how great a saving Mr. Smith effects in the item of fuel. The boiler, which is kept up with the refuse of the factory, costs, of course, nothing; whilst the two oil furnaces cost very little, as Mr. Smith has a contract for the supply of the crossote at a very low price, infortunately, proved only the failure of the of coaling at Gibraltar. Of the vessels on

# MACHINE FOR MAKING LUCIFERS.

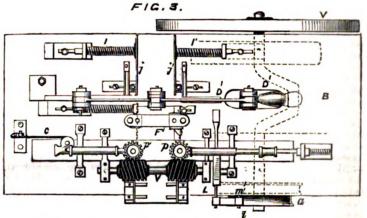

he North American station, the same may be said. The returns from the "Royal Alfred" are most satisfactory; a few catarrhs alone seem to have occurred.

Turning to the general view of the health of the navy, it appears from the report that during the twelvemonth the total force in the service afloat amounted to 50,340, the deaths 558, and of these 420 were occasioned by disease, and 138 by wounds and injuries. The rate of mortality was 11 per 1,000 or 3.7 below the average of the last twelve years. The highest death rate was observed in the China and west coast of Africa stations, being 21.7 and 20.4 respectively, accounted for by the occurrence of dysentery and cholera in China, and fevers on the west coast of Africa. The number of drowned amounted to 85 in all. The total number of cases entered in the sick list was 64,997, or 1295.7 per 1,000, an increase of 39.9 per mille over the rate of the previous year, and 144.2 less than the average of the last twelve years. On the East Indies and Cape station the sickness was in large amount, 2041 per 1,000, but this is explained by the fact that many vessels were employed in the Red Sea upon the Abyssinian expedition, and the men in them were harassed by hard work and multifarious duties in an unhealthy climate, and under exposure to the sun, the prevailing illness having been of a febrile nature. As to the invaliding, the ratio was 34.7 per 1,000 of mean force—about the average. The rates for the several stations average. The rates for the several stations were as follow:—Home, 21·3; Mediterranean, 27·8; North America, 41·6; South-East Coast of America, 25·9; Pacific, 44·5; West Coast of Africa, 86·5; East Indies and Cape, 77·9; China, 61·9; Australia, 17; irregular force, 25·9 per 1,000. On the whole, we may congratulate ourselves upon the general improvement which has taken place in the health of our navy during the place in the health of our navy during the last few years, and which cannot fail to increase as sanitary measures are more persistently insisted on and strictly carried out.

# MACHINE FOR MAKING LUCIFERS.

IN a memoir presented to the Société des Ingenieurs Civils, by M. Henri Peligot, it is estimated that the daily consumption of lucifer matches in France, is at the rate of half-a-dozen per head of the population. The proportion for England is as high as eight, and it reaches nine for Belgium. Basing the estimate upon that of six per head per diem estimate upon that of six per head per diem,

the daily consumption of these useful little articles throughout the whole of Europe will be over two thousand million. The weight of lucifer matches varies considerably. Those most in use in France give about 1,340 to the pound, while the same weight will yield three times as many of the round and square description common in Austria and Sweden. Striking an average, and assuming 1,700 as the datum, the daily quantity of wood con-sumed in their manufacture would amount to three hundred tons. Poplar and aspen are the trees generally felled for the production of matches. The weight of the former per cube foot is equal to 27lb., and that of the latter to 40lb. As timber, however, is purchased in the log, an allowance must be made for waste, and taking the mean of the two descriptions of timber, the cube foot would only weigh, when squared and reduced to actual available dimensions, about 20lb. Again, an allowance must be made for loss by sawing and other causes that will arise before the wood becomes converted into the marketable article. Summing up these several deductions, it will be found that out of a cubic foot of rough unhewn timber not more than a quantity equal to 18lb. will be practically utilized. Upon this supposition, the annual consumption of timber for the manufacture of lucifer matches throughout the whole of Europe will amount to 14,800,000 cube feet, or 296,000 loads, reckoning 50 cube feet to a load.

The manufacture of matches is a branch of the industrial arts, that has given rise to the formation of several important establishments

one in Austria employs 5,000 workmen, and the MM. Four et Cie, of Marseilles, have work enough for 1,000 more. It is calculated that upwards of 50,000 persons are concerned in the fabrication of these articles in the various countries of Europe, and that the value of their production reaches the figure of £120,000. Before describing the action of the machine represented in the accompanying engraving, a brief mention of the general operations attending the manufacture of lucifer matches will not be without interest. The first step consists in cutting up the blocks of wood, which may be accomplished with the saw, the knife, the machine, or the plane. When the knife is the instrument employed, the block is cut at once to the required length. It is then cleft twice in opposite directions by a large knife strongly resembling that used by bakers, and by these means small thick pieces are produced ready to be "dipped" previous to undergoing the final operations. The dipping is simply plunging one end of the wood into a quantity of sulphur in a state of fusion, and the next process is effected by inserting the sulphurized extremity into a pasty chemical preparation, which is spread out upon a marble slab to the thickness of about the tenth part of an inch. The cutter of the plane used to divide these small blocks into single pieces has a peculiar formation. It is composed of a flat quadrangular bar, of cast steel, 5in. long, half an inch broad, and a quarter of an inch thick. This bar is slightly turned up at one end, and thinned down by the file. Three cylindrical holes are drilled in it, which become the cutters which divide the block into and firms for that particular purpose. A large small round parcels. Some planes have five

More-

holes in them, and consequently can subdivide a block into five smaller pieces at one blow. The blocks are in lengths of about 2ft. 6in., and the blow of the plane being given along the entire length, they are at once divided into three or five smaller pieces. These are made up into bundles and tied together with strong twine. Subsequently, the cutting of these bundles into their proper lengths for lucifers is accomplished either by a knife similar to that already described, or by a circular saw. The whole operation is conducted with extreme rapidity, a single workman being able to cut up blocks in one day sufficing to furnish 2,000,000 matches. If the plane commonly employed in the Austrian establishments be supposed to be converted into a machine, it will give an excellent idea of that in ordinary use in France. The cutter of the plane is pierced with either three or five holes, and at every forward stroke cuts the block into as many subdivisions as there are holes in the cutter.

As may be expected, there have been numerous patents taken out for machines to accomplish rapidly and effectually the operations just described. That illustrated in the accompanying cuts has been recently patented by M. Charles, and presents some novel and interesting features.\* One of the principal of One of the principal of these is, that it cuts the wood in such a manner as to leave a certain portion, forming either the top or bottom of the packet, uncut, so that it ties the matches, as it were, together. Consequently, a single match can be detached from the rest, without destroying the union and apparent solidity of the remainder. machine is represented in figs. 1, 2, and 3, in elevation, section, and plan. It is supported upon a stout frame or table B, underneath which are bolted on a pair of brackets, carrying, by means of journals, the cranked shaft A, which is set in motion by the application of any force applied to the driving pulleys a. At the other extremity of the shaft is fixed the flywheel V, and close to the pulley is attached the eccentric b, which regulates the rate of advance of the block to be operated The eccentric b also acts upon the small cranks m m 1 (see figs. 2 and 3) which are fixed in succession upon the little axle l. The crank m 1 is connected by a double spindle to the rod L, which acts upon the tooth wheel R attached to the axle v. This latter carries an endless screw, v and v working in the pinions p and p, and, consequently, setting in motion the grooved cylinders C C  $^1$ , which regulate the movement of the wooden block undergoing incision. The cylinder C is undergoing incision. kept in a constant position, but C<sup>1</sup>, through the medium of the cord c which suspends a weight of about 35lb., exercises a constant pressure, sufficient to move the block, which nearly balances the above weight. Figs. 1 and 2 show the knife H, to which a vertical, rectilineal and alternate motion is imparted by means of the lever D and the rod D, one end of the latter being attached to the cranked shaft A (see fig. 1). It will be seen that the knife is hafted into a handle &, which, by means of a screw, can be raised or lowered at pleasure, so as not to allow the knife to descend low enough to cut the wood right through, and thus destroy the distinguishing characteristic of the machine. A plate of iron, F, is maintained by the screw SS<sup>1</sup>, pressed tight against the block of wood, so that it ugnt against the block of wood, so that it should not spring under the action of the knife. The block of wood advances by the motion of the grooved cylinders C C¹, between two girders j and j, between which is a plate acted upon by a spring. This plate serves to keep the blocks in a proper position, notwithstanding the various thicknesses that may be given to them. All the component may be given to them. All the component parts of the machine are so arranged that they may be taken to pieces and readjusted with ease and rapidity. Those who know what an inconvenience it is to upset a whole box of

\*We extract the cut from our valuable cotemporary
"Le Genie Industriel."

matches in the attempt to extract one, will appreciate the value of the principle which permits one to be detached, while the remainder retain the shape and consistency of an apparently solid mass.

## THE HEATON STEEL PROCESS.

N view of the important advantages which I will accrue to our great manufacturing industry from the introduction of the Heaton process of making steel from iron of inferior brands, it is satisfactory to know that the commercial features of the undertaking are prospering. Just a month since, we noticed the progress of this invention, which had previously been described by us in all its details.\* In our last article, we discussed the correspondence which had taken place in the "Times," between Mr. Heaton and Mr. Bessemer, and which embodied numerous points of working detail that substantiated both the value and the validity of the invention. have now to draw attention to the commercial phase of the question, which, as will be seen by the prospectus of the "Heaton Steel and Iron Company," in our advertising columns, is highly satisfactory. cipal portion of the capital has already been subscribed, and one-fourth of the shares is now offered to the public as preference shares. It appears from the articles of association of the company, that these shares will be enti-tled to a prior dividend for each current year of 6 per cent., and an additional dividend of 25 per cent. of the net surplus profits. No monetary consideration is to pass to the pro-prietors of the patents for the purchase of their interests, nor are those parties to par-ticipate in any profits whatever until the dividends on the preference shares have been paid. Indeed, a more favourable prospectus could not be presented to the public, who will not be slow to appreciate the terms offered to them, based as they are upon an invention which has proved itself a thorough success from practical working. The merits of the process are further established by experi-ments which have been carried out by Pro-fessor Miller, Mr. Robert Mallet, and a French commission under Professor Gruner, whilst the iron and steel produced have been proved to be of a highly satisfactory character by Mr. Kirkaldy's testing apparatus. In short, we are glad to see that both from a scientific and a commercial point of view, the Heaton pro-cess promises to mark an important era in the history of the iron and steel manufacture of Great Britain.

### DICTIONARY OF ENGINEERING.

A NEW dictionary, or any species of book, of the character of an encyclopædia, must, throughout every portion of its multifarious cortents, in some degree resemble the "latest edition" of a daily journal. Every subject upon which it professes to treat, either sparsely or in detail, must be illustrated by the most recent examples, and the old school of ideas, words, and deeds discarded for the more modern scientific and enlightened principles of thought and action. That there are several very excellent works of the nature alluded to, already in existence, every engineer is aware of, but not one of them can be considered to lay the smallest claim to the title of modern. When we turn a reflective glance at the enormous strides that every branch of engineering has made during the last twenty years, it will be admitted that a literary production, embracing all the prominent features of the different phases of the profession, was very much needed. Judging from the three numbers of "Spon's Dictionary of Engineering" that

have already appeared, we consider it well adapted to supply the present deficiency. At the same time, there are a few points in which there is room for improvement, and in order to indicate these for future revision, we will briefly scan the contents of Nos. 1, 2, and 3. There appears to be a little typographical slip in the article "Adhesion," where the decimal point has been placed after the values given for c, and which confuses the meaning. That this is an error is plain from the fact that it is omitted in the equation  $c \times t \times b$  560  $\times$  18  $\times$  99·68

over, written as 560; it is an absurdity. The greater portion of No. 1 is absorbed by "Agricultural Implements," a subject which is treated as fully as it deserves. There are few large farms upon which some of the more improved agricultural machines are not employed. Those of our readers who have visited our great national agricultural shows, cannot fail to have witnessed the large number of implements forwarded for trial, from the insignificant bruisers and pulpers to one of Howard's mammoth steam ploughing machines.

It might be questioned whether sin. z, and other abbreviations employed, can be strictly included under the head of "Algebraic Signs." We should consider many of those included under that title to be, correctly speaking, geometrical and trigonometrical signs. Considered as a whole, the subject is signs. Considered as a whole, the subject is treated in a most compendious manner. In our opinion, the brief notice of Mr. Byrne's dual arithmetic might have been omitted with dual arithmetic might have been omitted with advantage. It is utterly impossible to gain the slightest knowledge of the meaning of the symbols employed, from the few lines relating to them; and, as they are not explained, it is difficult to guess for what purpose they were introduced. At the same time, the whole principle may be hereafter fully explained with propriety under the head of "Arithmetic." Under the head of angle iron, the same disregard to classification is observable as that we have already noticed in "Algebraic Signs." classification is observable as that we have already noticed in "Algebraic Signs." In addition to sections of angle iron, others illustrative of channel, tee, sash, and numerous other forms, are also given. These, in reality, have nothing whatever to do with the title, and should be mentioned under their respectively distinct names, or included as a variety of the general species, "Iron." These little blemishes, which can "Iron." These little blemishes, which can be easily removed as the work progresses, do not detract from its intrinsic merit, nor interfere with the result aimed at by the publishers, which is to furnish the members of the profession, and the public generally, with a valuable book of reference and authority. Besides the vernacular names of the subjects appearing, they are also rendered into French, German, Spanish, and Italian. As will be expected, in many instances it is necessary to employ a paraphrase. The necessity for this is partly owing to the fact that there are many detail branches of engineering and mechanical industry, which, however common with ourselves, are not represented in other countries. In fact, it is not an uncommon occurrence for many of our own words to be adopted by the majority of the continental nations, with only the slight difference occasioned by individual pronunciation. The dictionary is abundantly illustrated by cuts and plates, and the get up of the numbers sustains the well-known reputation of the firm as scientific publishers.

# RATEABLE AND NON-RATEABLE MACHINERY.

A WORK on the principles of rating is not one which appears at first sight calculated to carry much interest with it to the majority of our readers. But on a closer

Digitized by Google

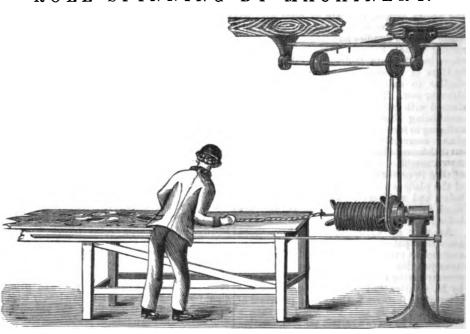

<sup>\*</sup> MECHANIOS' MAGAZINE, October 30, 1868. † "Spon's Dictionary of Engineering: Civil, Mechanical, Military, and Naval; with Technical Terms in French, German, Italian, and Spanish." London: E. and F. N. SPON, 48, Charing-cross.

inspection of the volume now before us,\* we have arrived at a very different conclusion, and, therefore, gladly draw attention of steam power users and others, having machinery on their premises, to some very important features in the work. "Penfold on Rating," is not a new work, the fourth edition having appeared in 1860. Since that date, however, no less than three Acts of Parliament bearing upon the subject of rating have been passed, besides which various important legal decisions have been given which materially affect the question. It was quite time that a new edition appeared, and a fifth has, there-fore, just been published by Messrs. Knight, which has been ably prepared by Mr. Kershaw, of 37, Norfolk-street, Strand, a surveyor of great experience, and an authority in all matters connected with the assessment of property. The present volume, there-fore, will be the means of throwing much light upon the application of a difficult and uninviting branch of the national economy, and will be of great assistance as a standard book of reference to the members of the various union assessment committees throughout England and Wales, in revising their valuation lists. But the points of the book to which we would invite the special attention of our readers, are those which relate to the rateability and non-rateability of the various classes of machinery. This question, which has of late given rise to a considerable amount of discussion, is very fully treated in Mr. Penfold's work, Mr. Kershaw having given special attention to it. He gives very concisely all the recent decisions of the Court of Queen's Bench on the subject. The work embraces practical considerations upon the principle of rating railway, gas, water and other companies, land tithes, buildings, manufactories and other properties, so that all are more or less directly interested in the matter upon which it treats. But we especially commend it to those who may occupy buildings in which machinery is fixed, and who do not know their exact legal position with regard to the rating of such machinery. They will here find all the information they require, with decisions of the judges both as to the rateability and the non-rateability of machinery.

# **TROLL SPINNING BY MACHINERY.**

A LITHOUGH roll tobacco, under one name or other has for or other, has for many years past been largely produced by our tobacco manufac-turers, it is a remarkable circumstance that until very recently only the most primitive process of hand spinning has hitherto been employed. In almost every other department of industry, machinery has long since superseded the slow and tedious process of hand manufacture. In this one, however, manual labour is even now, in some instances, employed—a piece of short-sightedness for which it is difficult to account in this boasted age of progress. Indeed, until a few months since, no change was ever attempted in the mode of procedure employed in the fabrication of roll tobacco. The first man who spun the first yard of pigtail ever manufactured in this country would perform his task precisely in a similar manner as some of his successors of the present day. He worked at a long, straggling, clumsy-looking table. At one end of this table there was a still clumsier and uglier looking kind of bobbin. This bobbin, actuated by a strap, was made to revolve by either a little boy or a little girl. These children worked like so many little galley slaves eight or ten weary hours daily-at their dreary, monotonous, and badly paid labour. Such was the condition of things at the tobacco factory of Messrs. Thomas Cope and Co., in Lord Nelson-street, Liverpool, when that

# ROLL SPINNING BY MACHINERY.

firm, with the praiseworthy view of ameliorating the evil, and, aided by an engine driver in their employ, effected a very beneficial alteration in this respect. The engine driver tried the experiment of turning the wheel by means of a piece of rope which was passed over a pulley on a shaft near the spinning table. The speed attained by this means was all that could be wished, and the bobbin was all that could be wished, and the bobbin was turned just as well as by a child. Messrs. Cope saw this, and determined that infantile labour should be superseded in their factory by engine power. To further this object, they at once employed a Mr. Hunter, a machinist, who soon worked out a simple system of cone pulleys and throwing-off gear, which was found to answer the purpose admirably. Soon after this, however, the new Factory Act came into operation, and the new Factory Act came into operation, and its regulations with reference to the employment of children were stringently carried out in the roll departments of tobacco factories. Manufacturers began to feel this anything but pleasant, and were aroused from their hitherto lethargic condition in the matter. interests were at stake, and they saw at once that some mechanical arrangement for turning the spinning-wheel had become absolutely necessary; in fact, could not, with any degree of convenience, be dispensed with. with these thoughts, Messrs. Cope were the first, we believe, to introduce a very simple system of overhead motion. With no other assistance than that afforded by pulley and strap, the speed of the wheel can be regulated so as to suit the different sizes of roll, and at the same time giving the spinner complete power over the rotary motion of the wheel. Messrs. Cope—to their credit be it stated exhibited their simple and effective invention for the benefit of the trade generally. The principles were found to be good, and, as a consequence, the system has been adopted by most manufacturers in the north of England. In the accompanying illustration, we give a perspective view of the spinning-wheel as it now works by the system of overhead motion, and which offers a marked contrast to the old style of working by a child. Messrs. Cope deserve every praise for the liberal manner deserve every praise for the liberal manner in which, in the interests of humanity, they have placed their arrangement at the disposal of the trade. The only wonder to us is that some such means were not devised long since, but it is not always easy to shake off settled habits and to get rid of antiquated ideas. However, Messrs. Cope have initiated a step in the right direction, which must now notens

volens be followed in all directions.

# ELECTRICITY AND TELEGRAPHY.

THE manufacture of the cable intended for the Persian Gulf has now been some little time completed at Mr. Henley's works at North Woolwich, and the whole of it coiled on board the ships "Calcutta" and "Tweed"—the major portion on board the former. The "Calcutta" left Gravesend on Friday, January 29, towed by a tug down Channel, and, on the following Friday, she proceeded on her voyage alone, but, as we now write, we have heard of a most disastrous termination to her voyage. On the Saturday night, she came into collision with a Prussian barque, which sank almost immediately; the "Calcutta" was so much damaged that she became almost waterlogged, and, to lighten her, the whole of the cable in the fore tank, about 70 miles, was run out, and the end buoyed. Some of the crew landed in ships' boats others were brought in; and there are fears that some of the men are lost, but at present it is impossible to say. It is hoped that all will be saved. H.M.S. "Terrible" and a tug left Plymouth in search of the vessel, and have just returned with the "Calcutta" in tow. The "Tweed," with the remainder of the cable, is all ready, and was appointed to leave this week, but, in the face of this awfully sudden catastrophe, it is not known what plan will be adopted.

The following is a satisfactory proof of the inreasing demand for telegraphy in America:-In 1867, the Western Union Telegraphy Company delivered to the press in that country 294,500,000 words of news matter, at a cost of 34 cents for a message of twenty words. This is at a cost of ene-fourth the ordinary rates. In the United States, the telegraph system is said to consist of 50,000 miles of line, 100,000 miles of wire, and 4,126 stations, and also 265 miles of submarine

A small vessel has been fitted out in America, A small vessel has been litted out in America, with the necessary picking-up apparatus, for recovering the lost Cuba cable. Sir Charles Bright has been with her for some time at Havana, and weather, it is understood, has delayed the operations. Our latest news, however, was to the effect that the vessel had been out and had returned to Havana with damaged out, and had returned to Havana with damaged machinery. If such should be the case, the recovery of the cable will be still further delayed.

A new frictional machine has lately been con-structed at the laboratory of the Sorbonne in Paris by M. Ferdinand Carré. On the same axis are mounted two discs of non-conducting material. The first, of gutta-percha, passes between two friction cushions, and is provided with a brass con-

Digitized by Google

<sup>• &</sup>quot;Practical Remarks on the Principle of Bating." By CHARLES PENFOLD, Surveyor. Fifth edition, rewritten and extended by JOHN THOMAS KERSHAW. London: KNIGHT and CO., 90, Fleet-street. 1869.

uctor furnished with combs. The second disc is arger than the other, but is not provided with sushions—only with a conductor and combs. The action in the second is that of induction, and in surning the handle powerful results are obtained rom this machine; so much so, that with discs of rom 14in. to 19in. in diameter, sparks have been btained varying in length from 5in, to 7in.

On some land lines constructed in America, telegraph poles were used made of the following kinds of timber—chestnut, cedar, and locust. It was found that decay set in more rapidly with the chestnut than with the cedar, and with the cedar more than with the locust; in fact, at the end of five years, the locust wood was nearly sound, whils

the others were much gone.

The Secretary of State for War has issued instructions that in future the superintendence of the working arrangements of all permanent military telegraph stations, electric and visual, as well as the construction of military telegraphs, shall devolve on the Royal Engineers, who will in future consider this as one of their regular duties. All officers and others of the corps who may be selected omicers and others of the corps who may be selected will be required to go through a course of instruc-tion in electricity and telegraphy; and in the method of constructing telegraphs, in the School of Military Engineering at Chatham. Electricity has already for some time formed a part of the engineering instruction at Chatham. The lectures on the subject were delivered last year by Pro-fessor Fleeming Jenkin. The course this year is to be on "Practical Telegraphy," and will be given by Mr. R. S. Culley, the Engineer-in-Chief of the Electric and International Telegraph Company. The British Indian Submarine Telegraph Com-

pany, whose prospectus we lately noticed, has progressed satisfactorily. The share list has closed, and, after a good subscription, the general allotment has taken place. We hope to report in an early number some energetic measures for the

furtherance of this great work.

Messrs. Siemens have commenced to make at their works the submarine cable intended to be laid in the Black Sea, from the Crimea to the Asiatic coast, forming part of the new Indo-European Company's overland line to Teheran.

A scheme was brought forward some few years

since for the establishment, at various necessary points, of light vessels, provided with means for rescuing life, and a system of signals, so that signals from vessels might be received and forwarded to the nearest point of land, by means of submarine cables from the vessel to the shore. It appears this scheme has again been brought forward, and is supposed to be under the consideration of the Government and the Trinity Board, the object being to moor floating telegraph vessels in the Channel, first, between the Scilly Isles and Ushant, and, subsequently, at the southern entrance of St. George's Channel, and of the extremities of Ireland. Communication is to be maintained with the nearest point of land by means of submarine cables. In addition to providing a means of communicating with the shore, it is proposed to make the vessel a sort of landing stage for passengers, so that people might disembark there, and reach the shore by local steamers plying to the nearest port; in addition, it is intended to store the vessel with the most needful of provisions, &c., so that the wants of windbound homeward vessels might be relieved.

In most of the places mentioned, the water is not too deep to admit of a vessel being moored, but as in each case it will be in a tideway, it will be necessary, for safety, to moor her so that she could always swing to tide, with a strong chain safely and securely moored in a manner similar to our light vessels. There is but little fear of a well-built suitable vessel riding out very severe gales; but so far as is at present reported, we are unaware how it is intended to arrange the submarine cable; this would in all probability hang down in a curve towards the bottom. The shifting of the vessel when she swung round to the different tides would infallibly kink the cable, and finally cause its breaking, if the friction it received on the bottom had not brought about a similar ending. By a peculiar system of attachment to the mooring chain and moorings, it is possible to obviate, in a great measure, these evils, but the practical experience already gained of submarine cables hanging from a ship for a continued length of time is decidedly against their lasting.

The manufacture of the French Atlantic cable is steadily and satisfactorily progressing at the cable works at Greenwich and at Woolwich. At the present time, about 1,400 miles have been manufactured at the former works, and 350 miles at the latter, making a total of 1,750 miles. Shipping on arrive at.

board the "Great Eastern" has been going on for some time; two vessels have already left the works at Greenwich, and discharged their cargo, mile by mile, into the "Great Eastern"; a third cargo, in the contractor's vessel, the "Scanderia," will leave in a day or two. The total amount of cable on board the "Great Eastern" is 740 miles.

OTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-NOTES PLICATIONS.

POISONED SOCKS AND STOCKINGS-MAGNETISM OF MOLTEN CAST IRON--COMBUSTION UNDER PRES-

SOME of our readers may remember a Mr. Webber appearing before the Lord Mayor to give publicity to the fact that stockings dved with a certain red dye produced, when worn, very severe irritation of the skin, somewhat difficult to cure. Cases of this kind have come under the notice of several medical practitioners, and within the last few days advertisements have appeared in the daily papers announcing the formation of a committee to investigate the subject of "sock and shirt poisoning." The work has already been done for them in Germany and France, where similar cases have been observed. In the former country, Dr. Bidard, after a full investigation, and, since then, M. Tardien, of Paris, have come to the conclusion that the cause of the mischief is corallin or coraline (from the colour of coral). This dye was first prepared by Wurtz from carbolic acid, and a process for its production was afterwards patented by MM. Guinon, Marnas, and Bonnet. It is made by first treating carbolic acid with oxalic and sulphuric acid, and afterwards with ammonia. The colour is probably rosolate of ammonia. Whatever it may be, however, dandies and girls of the period have suffered severely from wearing silk socks and stockings dyed with it, and its use should be discontinued. It does no internal mischief, but applied to the skin brings out a pustular eruption It may be that a new ccunter-irritant has beendiscovered which the doctors will appreciate.

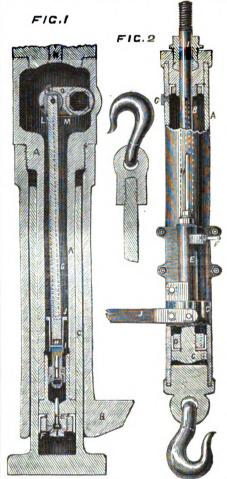

An ordinary magnet loses its magnetism when heated. But molten cast iron, surrounded with a helix, through which a strong galvanic current is sent, becomes strongly magnetic, and retains its magnetism as long as the current is continued. This fact has been discovered by M. Treve, who draws some important inferences as regards the

magnetism of the earth.

Some time ago, we laid before our readers Dr. Frankland's views of the cause of luminosity in a flame. In opposition to Davy's opinion, that luminosity nosity depends upon the incandescence of solid particles, Dr. Frankland asserts that it is a consequence of the density of the atmosphere surrounding a flame. We need now only mention one experiment which is thought conclusive. The flame of pure hydrogen, which is barely visible at the ordinary pressure of the air, becomes more and more luminous as the atmosphere in which it is burning is compressed.
M. Deville does not accept Dr. Frankland's conclusion. Pressure, he says, means elevation of temperature, and luminosity depends upon temperature. It is not our intention to enter upon this discussion here, and we come at once to a practical application. Pressure meaning elevation of temperature, M. Deville suggests that the furnaces of engines might be supplied with air under pressure, in which case the products of combustion passing slowly through tubes at a much higher temperature than under ordinary conditions, the extent of the heating surface might be greatly diminished. The application to marine boilers when heated with liquid hydrocarbons is particularly mentioned, and is, perhaps, within the range of possibility. Double work, however, it must be remembered, is imposed on the steam, and the requirement of an extra boiler might counterbalance the advantages of a diminished heating sur-We look forward with much interest to the results of M. Deville's labours. He has had an iron room constructed in which he can carry on furnace experiments under a pressure of two or three atmospheres, and we sincerely hope that no accident may happen to prevent him from giving to the world the valuable results he is likely to

# HYDRAULIC LIFTING AND PULLING

WE herewith illustrate some improved forms W of hydraulic jacks, which were designed by their manufacturer, Mr. J. P. Baragwanath, of 200, Upper Thames-street, London. Fig. 1 represents a vertical section of the lifting jack, from which it will be perceived that the ram A is protected by an outer casing B, which prevents any grit or dirt getting into the working parts. At the bottom end of the casing B a claw is attached the bottom end of the casing B a claw is attached for lifting loads from the ground. The head of the ram forms the reservoir. On raising the plunger D the valve opens and allows the water to flow through into the pump, and closes on depressing the handle, at the same time forcing the pump full of water through the lower valve the cylinder C, thus raising the ram with its load through a space equal to the pump full of water distributed over the area of the cylinder. In lowering the ram, the valves are both opened by withdrawing the handle a little in the socket, so as to allow the projection on its end to clear the stops on the head of the ram, and then depressing the lever down to its full extent; by so doing the bonnet at the bottom of the plunger D presses on

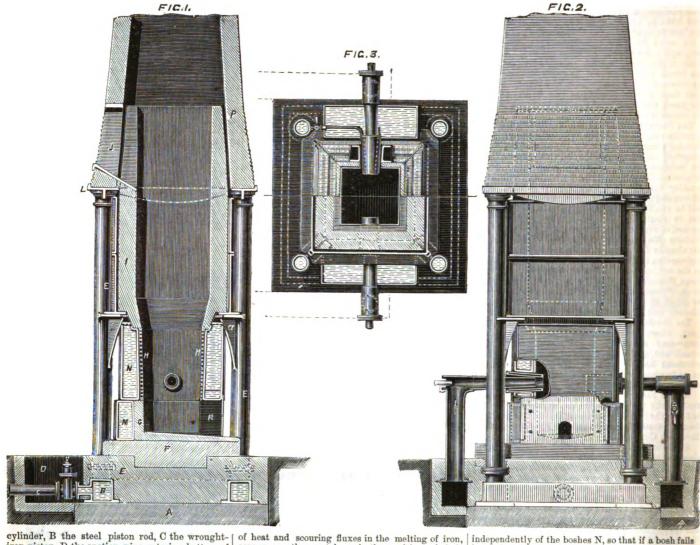

the valve F and opens it, allowing the water to flow upwards. At the same time, the pin I presses against the valve in the plunger D, and opens a passage for the water back into the reservoir, which is then ready to be pumped into the cylinder again for a further lift. Having dispensed with all spiral springs, and made the machine as simple as possible, there is no chance of the working parts being put out of order by rough usage. The valves and working parts can be readily got at by unscrewing the top of the head, and all the interior working parts can be drawn out for examination. These jacks are made in sizes to lift from 5 to 40 tons, the smallest weighing 55lb., and the largest 200lb. They lift at double the speed of the best screw jacks, and are quite safe in lifting and lowering. The advantages claimed by the inventor are protection and simplicity of the work-ing parts, lightness, speed in lifting and lowering, and the small amount of manual power required in working them. They are in use on several railways, and at the works of some of our leading ship builders, engineering and boiler makers,

where they are deservedly appreciated.

At fig. 2 is seen the pulling jack in vertical section. In this tool, A is the wrought-iron

#### IMPROVED SMELTING FURNACE.

BY MR. JOHN THOMAS.

cylinder, B the steel piston rod, C the wrought-iron piston, D the suction pipe entering bottom of the cylinder, E a force pump bolted to the cylinder, F the cock for lowering the cylinder, G the filling hole, H a delivery pipe entering the top of the cylinder, I the stuffing box for the piston rod, and J the lever for the handle to fit on for working the pump. The jacks are shown in position ready to pump. The jacks are shown in position read, be lowered to attach a load. To operate it, first be lowered to attach a load. To operate it, first open the cock F, and on pressing the handle of the pump down to its full extent, it opens the delivery valve of the pump (which is not shown). This allows the water on the upper side of the piston to pass through the delivery pipe H, through the delivery valve in the pump, and through the cock F into the suction pipe G, which enters the cylinder just at its bottom. The weight of the machine is sufficient to force the water from machine is sufficient to force the water from the upper side of the piston to its under side, when the cylinder is lowered to the depth required; next shut the cock F and attach the load to the lower hook, and on working the handle the load is hoisted. The load can be lowered at the load is hoisted. The load can be lowered at any speed required by partially or fully opening the cock F; when the load is hoisted, the machine will support the suspended load for any length of time. These jacks are made to lift from 2 to 15 tons; the smallest weighs only 50lb., and the largest 180lb. They are found useful by marine engineers, marry of whom have adopted them for lifting, available, covers and published the states. lifting cylinder covers and pulling-out pistons.

They are also useful for many purposes on board ship, such as stretching shrouds, rigging, &c.

These jacks are well worthy the attention of those firms who are not yet using them, as effecting a great saving in time in the many operations to which they are applicable.

# IMPROVED SMELTING FURNACE.

THE chief object of the invention illustrated in the annexed engraving is to construct air or blast furnaces which will the better withstand the action

or heat and scouring fluxes in the melting of iron, copper, or other metals, or in the smelting of their ores. The main features of this invention, which has been patented by Mr. John Thomas, of Newcastle-upon-Tyne, in addition to the general arrangement of the parts, are the construction of water boshes, and the employment of spikes on the water boshes. Our engraving shows, at fig. 1, a sectional elevation; at fig. 2, a similar view at right angles; and at fig. 3, a sectional plan of one of these furnaces;

For a cupola or blast furnace, Mr. Thomas first makes a foundation A, and fixes therein a water pipe B, which passes completely round the furnace, except makes a foundation A, and fixes therein a water pipe B, which passes completely round the furnace, except at the front. There is a branch C to this pipe to let the water in, the branch being provided with a valve and a valve well D. There is also a branch at each corner of the pipe upon which is fixed the hollow columns E E. These columns are closed at the top, and an entablature is fixed on them on which the chimney is built. The water is let into the foundation pipe B from a high level so as to rise and fill the columns E E, the use of the columns being to hold water and carry the chimney. Brackets a a are cast on the columns to carry the plates O, which hold the upper brickwork of the furnace. Upon the foundation, Mr. Thomas builds as usual up to the bottom of the furnace, as shown at F. He then places water boshes M M, of cast or wrought iron, all round the furnace, except at the front, where there is a door R, as is usual in cupola furnaces, or a dam, as in blast furnaces. These boshes are set back 4½in from the face of the furnace inside, to allow of a thickness of lining G of firebrick. He then places another tier of water boshes N above those just described; these upper boshes go all round the furnace, or an all four sides. They have spikes h heart all another tier of water boshes N above those just described; these upper boshes go all round the furnace, or on all four sides. They have spikes b b cast all over their inner sides similarly to ironfounders' loam plates; these spikes may be of any suitable length, but  $1\frac{1}{2}$  in. is found to be sufficient for most purposes. The upper boshes against the spikes are lined with stiff mortar H H, made of refractory material, such as ganister and fireclay, or road grit and fireclaye On the brackets a a of the columns are placed the iron plates O O, which enclose the four sides. These plates reach nearly to the charging door J of the furnace. On the bottom edge of these plates there is a flange for carrying the brickwork I of the furnace,

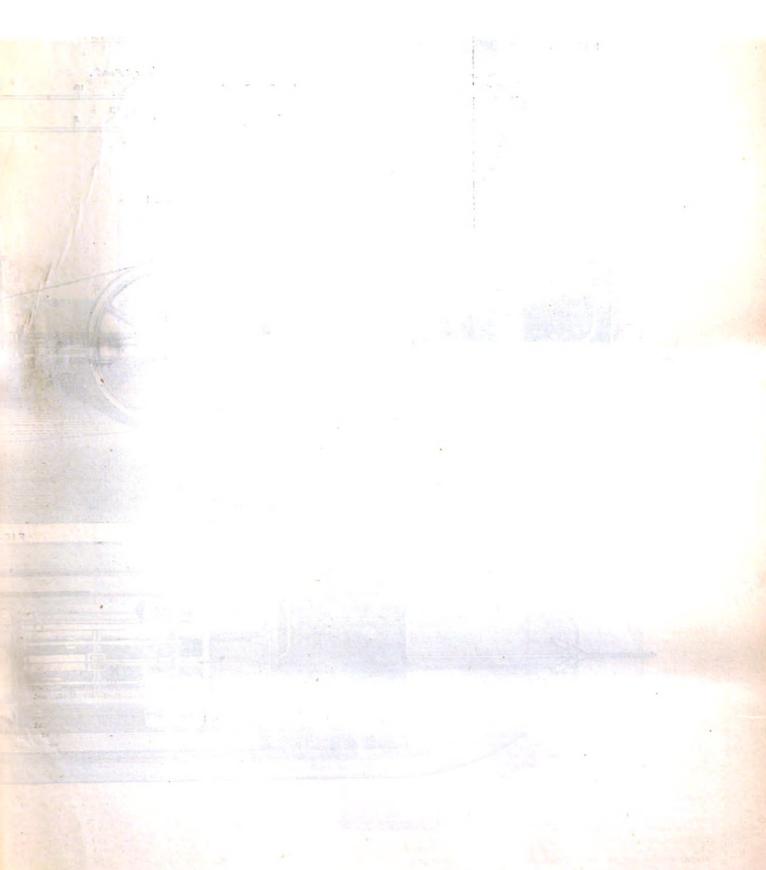

independently of the boshes N, so that if a bosh fails

independently of the boshes N, so that if a bosh fails it can be taken out and another introduced without pulling down the brickwork.

The inside of the furnace is next built up from the top of the boshes with firebrick or other refractory material. The boshes M and N are filled with water drawn from the columns E E by a pipe connected with the bosh and the columns; each of these pipes has a tap to regulate the supply. A hole is cast through the side boshes for inserting the tuyeres cc; there are water tuyeres also supplied from the columns E E, as shown in fig. 3. The inside of the furnace is similar in form to a blast furnace, larger at the upper part than at the bottom, and the crucible or lower part is made tapered. This form of furnace is best adapted to hold up the material under treatment, in order that it may be melted above the blast, and fall like rain drops, and gravitate through the fluxes. If desirable, the lower boshes are spiked and brought forward to the face of the furnace, and lined against the spike the same as the upper boshes. The principal novelty in this invention is the spiked boshes which hold up the lining, which cannot be fluxed away on account of the water in the boshes, keeping the back of the lining comparatively coal. boshes which hold up the lining, which cannot be fluxed away on account of the water in the boshes, keeping the back of the lining comparatively cool. For air or reverberatory furnaces for smelting copper or other ores of metals, the bed of the furnace is built in the usual way up to within 4in. or 6in. of the bottom. The spiked water boshes are then set around the sides and bridge of the furnace, and the spikes lined up against, as in the cupola or blast furnace. For a puddling furnace for puddling cast iron into wrought iron, the spiked water boshes are set round the sides and bridge of the furnace, as in the copper smelting furnace.

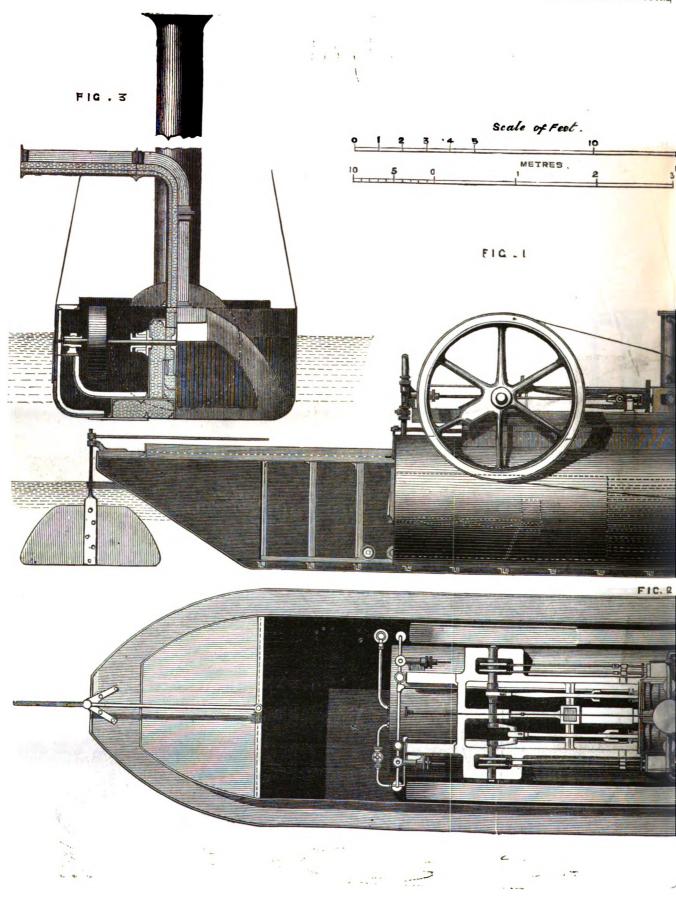

The champion ploughing match of the West Auckland Society took place on Tuesday week on a stiff loamy soil. Twenty-seven men competed for the prizes, and some excellent work was shown. All the prizes in the champion class—indeed, all the prizes in the field, with the exception of one third prize—were won with Messrs. Ransomes' ploughs. This makes the fourth match this year at which Messrs. Ransomes ploughs have, in local hands, carried off all the prizes in All England classes.

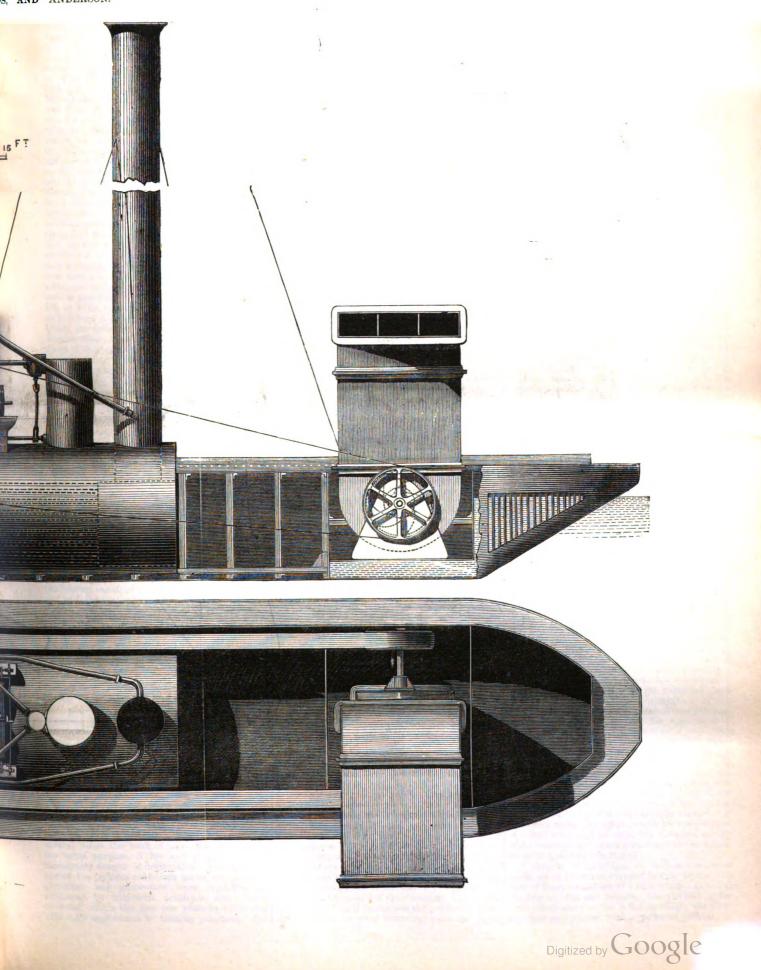

# FLOATING CENTRIFÜ

BY MESSRS. EASTONS,

# L DRAÍNAGÉ PÚMP.

S, AND ANDERSON.

## FLOATING CENTRIFUGAL DRAINAGE PUMP.

THERE are very many moderate-sized tracts of land in this country, and especially in Holland, which, if freed from the waters covering them would be valuable property. The cost of fixing pumping machinery powerful enough to effect this object deters even enterprising men from making any attempts, especially as the soft and even marshy nature of the ground generally renders the expense of works requiring solid foundations very uncertain. With a view to overcoming this diffi culty, the novel application of the Appold centri-fugal pump, of which we give a double page illustration, was designed by Messrs. Eastons, Amos, and Anderson, of London and Erith. Into a pontoon 52ft. long, 10ft. wide, and drawing 4ft. of water, is laid a very strong Cornish multitubular boiler, 21ft. long, and 5ft. 6in. diameter, with a 3ft. 6in. flue, and 4in. iron tubes. Upon a wroughtiron framework riveted to the back of the boiler is laid a pair of non-condensing engines, with 12in. cylinders, 20in. stroke, provided with double slide valves for variable expansion. The flywheels of the engines act as driving pulleys, and transmit the power through two 10in. belts to the pulleys on the spindle of the centrifugal pump, the fan of which, of the true Appold proportions, 2st. 7in. diameter, revolves in a wrought-iron case bolted to the bottom of the pontoon. The inlet pipes of the pump, also formed of wrought iron, descend to and are connected with a sort of false bottom, which opens into the bulkhead at what may be called the bow of the craft, which, though it have the semblance of a spoon-shaped bow, is in reality only a grating in disguise, the bulkhead being the true termination of the boat. The object of this arrangement is to get a horizontal inlet at as low a level as possible. The delivery pipes are sheet iron, 5ft. by 1lin., and are made in various lengths, so as to set up foot by foot as the level of the water sinks, the delivery finally being by a bend into wooden shoots over the nearest embankment. The speed of the engine varies from 80 to 116 revolutions per minute, according to the lift. The steam enters the cylinders at pressures varying according to the lift, up to 120, and is cut off at 3in. of the stroke, or about one-seventh, the exhaust steam being conveyed through a tubular feed-water heater and by means of a ring blast and petticoat, into the chimneys. The pump raises fifty tons of water per minute—a mighty stream to issue from a machine the proportions of which make it appear inadequate to so much work.

At a trial of one of these floating pumps, the engine made eighty-five revolutions, the lift was 6ft. 6in., steam 90lb., cutting-off at 3in., and the consumption of fuel was only 160lb. per hour. Under this high pressure and very sharp cut-off the engines worked very smoothly, and the whole the consumption of the state of the engines worked very smoothly, and the whole the consumption of the state of the apparatus appeared eminently adapted for its purpose. When in actual use it is steadied between six poles, which carry the shoots and a temporary roof to keep off the weather. When the land has been pumped dry either a dam is constructed round the pump and water let in to float it into the nearest canal, or the machinery is taken out, and with the boat, which only weighs about 91 tons, taken overland to its next field of operations.

## EXPLOSIVE COMPOUNDS FOR ENGINEER-ING PURPOSES.

By Mr. Perry F. Nursey. (Continued from page 106.)

THE most powerful opponents with which gunpowder apparently has to contend, are nitro-glycerine and gun-cotton, and this on account of the extraordinary amount of power they possess; indeed, under certain conditions, they develope an almost irresistible force. But it is just this attribute of resistless violence which has hitherto rendered them the most unsafe, the most dangerous compounds that can be applied to practical purposes Man loses all control over these agents, inasmuch as an accidental blow or a slight concussion may—nay, must--produce a violent and perhaps most disastrous explosion. It is of no avail to possess a material which does several times the work of any other adapted for the same purpose, if life and property are in momentary danger of destruction. That this was momentary danger of destruction. one of the perilous conditions under which nitroand gun-cotton were employed, is evidenced by numerous accidents which have the dangerous nature of their contents led to the occurred within the last few years in connexion with their application to blasting purposes. But strongly with the peril attending even the mere

both these dangerous agents have within the last twelve months been brought under control, and their action has been so modified that they may now be said to possess all the conditions necessary to constitute a safe and highly efficient material

for blasting purposes.

Taking them in the order in which they are referred to above, let us first examine the merits and demerits of nitro-glycerine, which is one of the most remarkable materials employed to replace gunpowder as a destructive agent. This substance was discovered by Sobrero, in 1847, and is produced by adding glycerine in successive small quantities to a mixture of one volume of nitric acid of sp. gr. 1.43, and two volumes of sulphuric acid of sp. gr. 1.83. The acid is cooled artificially during the addition of glycerine, and the mixture is afterwards poured into water, when an amber-coloured oily fluid separates, which is insoluble in water, and possesses no odour, but has a sweet pungent flavour, and is very poisonous, a minute quantity placed upon the tongue producing violent headache, which lasts for several hours. The liquid has a specific gravity of 1.6. and solidifies at about 5deg. Cent. (40deg. Fah.); if fame is applied, nitro-glycerine simply burns; and if placed upon paper or metal, and held over a source of heat, it explodes feebly after a short time, burning with a smoky flame. If paper moistened with it be sharply struck, a somewhat violent detonation is produced.

In 1864, Mr. Alfred Nobel, a Swedish engineer, as an explosive agent. Some experiments were, in the first instance, made with gunpowder, the grains of which had been saturated with nitroglycerine. This powder burnt much as a management, with a large state of the saturated with nitroglycerine. glycerine. This powder burnt much as usual, but with a brighter flame, in open air. When confined in shells or blast-holes, greater effects were, however, produced with it than with ordinary gundered with the state of the stat powder; its destructive action is described as having been from three to six times greater than that of powder. The liquid could not be employed as a blasting agent in the ordinary manner, as the application of flame to it from a common fuse would not cause it to explode. But Mr. Nobel has succeeded, by employing a special description of fuse, in applying the liquid alone as a very powerful destructive agent. The charge of nitro-glycerine having been introduced, in a suitable case, into the blast-hole, a fuse, to the extremity of which is attached a small charge of gunpowder, is fixed immediately over the liquid. The concussion produced by the exploding powder, upon ignition of the fuse, effects the explosion of the nitro-glycerine. The destructive action of this material is estimated to be about ten times that of an equal weight of gunpowder, so that if we take 32,000lb. as the average of work done by 1lb. of gunpowder, as stated in the early part of this paper, we get 328,320lb., or about 146½ tons, as the work done by 1lb. of nitro-glycerine. the work done by 1lb. of nitro-glycerine. Therefore, although its cost is about seven times that of blasting powder, its use is attended with great economy, more especially in hard rocks, a considerable saving being effected by its means in the labour of the miners, and in the time occupied in performing a given amount of work, as much fewer and smaller blast-holes are required than when gunpowder is employed. The material appears to have received considerable application in some parts of Germany and in Sweden; but, in England, it has not progressed beyond the stage of experimental trials.

Although nitro-glycerine appears to possess ery important advantages over gunpowder as a blasting and destructive agent, the attempts to introduce it as a substitute for gunpowder have been attended by most disastrous results, ascribable in part to some of its properties and the evident instability of the commercial product. The explosion which occurred on board the West Indian Company's steamer "European" will long be remembered by many. This distressing event happened on April 3, 1866, when the "European' was unloading her cargo alongside the railway company's wharf at Aspinwall. The force of the explosion was such as to tear away the upper a ts of the ship, and to blow the plates off her sides. The wharf, too which was some 400ft. in length, was literally torn to pieces, and about fifty persons killed, whilst many others were periously injured. By the ship's bills of lading a number of cases of nitro-glycerine were proved to have been on board, and doubtless careless handling of these packages by men who were ignorant of

transport of this destructive agent, another accident occurred on the 16th of the same month. oil-stained boxes, each measuring about 4 cubic feet, arrived at San Francisco by the Pacific mail steamer. They were removed from the ship into the city, in which they had no sooner been deposited than they exploded with a violence that shook the neighbourhood like an earthquake for a quarter of a mile around, and proved terribly fatal to human life. It was publicly stated that the boxes contained nitro-glycerine, which was intended for sale to the mining companies in Nevada, Idaho, and Colorado. In Sydney, New South Wales, too, a tremendous explosion occurred on March 4, 1866, in the stores of Messrs. Molison and Black, in Bridge-street, which were totally destroyed. The noise of the explosion is said to have very much resembled the discharge of artillery, whilst a column of the debris was thrown to a height of about 150ft. A great amount of damage a height of about 150tt. A gross-mount was done to the surrounding buildings, and proexplosion was traced to two packages of nitroglycerine.

There is vet another danger attending the substitution of nitro-glycerine for gunpowder in mining, and this relates to its manipulation when being prepared for firing a shot. Although the oil may have been safely transported to its destination, there is no guarantee that its destructive energy will not be developed before it is placed in the hole which is intended for it. Indeed, there are instances on record which show how slight a circumstance serves to spread death and destruction around, even in the handling of this material. It should be observed that among other disadvantages, nitro-glycerine freezes at a somewhat high temperature, in which condition mere friction will explode it. A sad illustration of this fact occurred in 1867 at Hirschberg, in Silesia, where nitro-glycerine was being used in the boring of a railway tunnel. The oil was one day found to be frozen, and in this state was delicately handled, and fragments were detached by means of a piece of wood. In the bore holes the frozen nitro-glycerine exploded quite as well as the fluid. One day and overseer attempted to break up a lump of the frozen material with a pick. The result was a violent explosion of the whole mass, which caused that the incautious miner. Several acceptance the dents have also occurred in our own country since the introduction of nitro-glycerine, and many of those who were the first to experiment with it have already given up its use. This material, therefore, worthy of utter condemnation for its fearfully dangerous and uncertain character, even under the most favourable circumstances. resistless energy is jully admitted, and its great value in this respect for mining operations duly recognized: but inasmuch as it does not appear that there are any conditions under which it can be handled with safety, its use ought certainly to be everywhere prohibited.

Such being the dangerous character of nitroglycerine, it is satisfactory to turn to this material in its modified condition. We will now consider this hitherto uncontrollable agent of destruction in a new form, in which it is comparatively harmless, and absolutely far safer to handle and transport than gunpowder. After long and patient experimental research, Mr. Nobel, painfully impressed with the danger attending the use of nitro-glycerine in its ordinary condition, succeeded in effecting a new combination, in which this treacherous compound is rendered perfectly innocuous, except under the actual conditions of work. To this new substance Mr. Nobel has given the very expressive name of "dynamite." It consists of fine gravel saturated with nitro-glycerine, in which condition it presents the appearance of coarse brown sugar. In July last some interesting experiments were carried out with this substance at the Merstham Greystone Lime Works, near Red Hill, Surrey, at which the author was present. So important were these experiments as bearing on the subject of the paper, that the author will here give their details from notes taken by him at the The object of the experiments was to illustrate the perfectly safe and harmless character of dynamite under any other conditions except those of actual work, and to show its resistless energy when confined and fired according to the speci mode proposed by Mr. Nobel.

A number of cartridges of various sizes were made up of dynamite wrapped in thin paper. To each of them was attached a fuse which burned at the rate of 18in. per minute. On the end of the fuse, which was inserted in the cartridge, was fixed a copper cap primed with a powerful detonating compound, and to which is due the development of the explosive energy of the dynamite. A charge of half an ounce of dynamite was first exploded on an oak plank about 6ft. long, 9in. wide, and 2in. thick, and supported at each end. An exceedingly loud and sharp report ensued, and an examination of the plank showed that the charge had taken effect completely through the board, the under side being rent and splintered. A similar charge was then fired on a balk of fir timber placed flat on the ground. A deep indent was made in the timber, and one side was splintered off. To prove the harmlessness of the dynamite when fired by an ordinary light, Mr. Nobel cut a cartridge in two and lighted one half in his hand with an ordinary fuse. It burned quietly and quickly, but not rapidly, out. The remaining half of the cartridge was then fired with a capped fuse, when a violent detonation resulted. The absence of all danger in case of collision or fire during transport or storage was then demonstrated in a most marked manner A small deal box, containing about 8lb. dynamite, was thrown down from the top of a cliff about 70ft. high, upon a hard bed of rock The concussion started the joints of the box, but the contents remained uninjured and unchanged. The test of fire was then applied to a similar box to the last, containing the same quantity of dynamite. A fire was kindled, upon which the box was placed, and after a few minutes the box quietly turned over on one side, a gentle puff of smoke and flame issued from it for a few seconds, and 8lb. of one of the most violent of modern explosives were almost noiselessly dissolved into air. The charred and blackened box was removed from the embers, and on examination the joints were found to be sound and whole. The author examined this box of dynamite before it was nailed down and placed on the fire, as also the one which was thrown down the precipice after the occurrence, and therefore writes from his own knowledge of the matter. Such tests ought to satisfy the most sceptical of the safety of the new blasting powder either in a railway collision, or accidental upset of a package, or a fire.

accidental upset of a package, or a fire.

The next point was to test the power of the dynamite when under conditions of partial and also of perfect confinement. To this end, about 40z. of dynamite were placed upon a block of granite measuring 3ft. by 2ft. 9in. by 2ft., the dynamite being only covered in with a lump of clay and a shovelful of gravel. A very loud report followed, and on examining the stone it was found to be traversed by rents and fissures. large masses to be traversed by rents and fissures, large masses being easily detached by a crowbar. The effect certainly surprising, considering the comparatively loose and unconfined condition of the charge. In the next experiment, a cynnurical block of wrought iron, about 12 in high and In the next experiment, a cylindrical 10½in. in diameter, and having a lin. hole bored through the centre, was used. The bore hole was but not rammed tightly—with dynamite. and fired. A report soon followed, remarkable for its penetrative loudness, and on examination one half of the cylinder was found about 80ft. from the place where it originally stood, being then only stopped by a grass embankment. The other half was found some 50ft. in an opposite direction, lodged against a pile of broken rock, which stopped its further progress. The iron showed a clean split, which revealed an excellent quality of metal. bore showed an extraordinary enlargement near the centre, measuring nearly 13in. across, whilst the measurements at the top and bottom of the bore were in each case lin., as before firing. It would appear that the power developed increased as it approached the centre of its length, becoming reduced again as it neared the further end of the hole although of course the explosion was practically instantaneous. Both ends of the bore were open to the atmosphere, there being no plugging nor tamping The strain on the metal must have been enormous to have thus compressed it around the centre of the bore, and to have rent such a mass and sent its halves yards away in opposite directions.

Although not strictly within the scope of the paper, it may not be uninteresting here to notice the experiments illustrative of the application of this powerful agent of destruction to military purposes. Dynamite is of course unfitted for use either in beavy guns or small arms, its very power being against it in this respect, as forcibly illustrated in the experiment with the cylinder. But it can be utilized in shells with great advantage. A time fuse fitted with the detonating cap would effect its explosion at the proper moment, whilst, if the shell broke up in the gun, no harm would result, as demonstrated by previous experiments.

he fairly met the point by filling a tin case with 411b. of dynamite, and firing it behind a piece of ratio of dynamice, and firing it behind a piece of curved in wrought-iron plate, 2ft. high and 3ft. long, measured round the curve. The plate was broken into four unequal parts, which were blown considerable distances away. The face of the plate upon which the powder had acted was completely pitted with small below doubtless to the atoms. pitted with small holes, due doubtless to the atoms of silica in the dynamite. This experiment satis-factorily demonstrated the great velocity which would be imparted to fragments of shells charged with this explosive.

The next experiment was directly illustrative of the present subject—that of blasting rock. Here a charge of 12lb. of dynamite was inserted in a vertical bore hole 15ft. deep and 2in. in diameter tamped with sand. The explosion was indicated by a low subterranean thud and a perceptible stremour of the surrounding land, even at a considerable distance from the blast. The rock showed a series of fissures which indicated that an enormous mass had been loosened, and was ready to be detached by the pick. Had the rock been of a harder and less friable nature, it would have offered a greater amount of resistance, and the whole mass would doubtless have been blown This was the case with some granite quarries out. at Stockholm, where an immense mass was de tached by a charge of dynamite, and thrown down in huge blocks. On the present occasion, a further charge of 41lb. of dynamite was fired at the same depth as the last, with proportionate results. One of our members, Mr. A. E. Walton, who was present at the experiments, and who is constantly engaged in blasting operations, affirmed that the results greatly exceeded his expectations, considering the comparative smallness of the charge. The method of charging in dry ground was next illustrated by filling a glass tube with a series of cartridges which were tamped with loose sand and This experiment was repeated with water tamping to illustrate the mode of operation in wet A striking effect was produced by firing ground. a cartridge in a bucket of water. The detonation appeared to be stronger than under any other conditions; the bucket was shattered, and fragments were picked up several hundred feet from the spot where the charge was fired.

It will thus be seen that the most severe tests for fety failed to show that any danger was pr in this material, whilst, on the other hand, there was no condition under which its violence was not developed when fired with a detonating fuse. So far, dynamite appears to be well calculated to supersede gunpowder for blasting purposes. only point of doubt which has arisen in the author's mind is whether any mechanical or chemical change might not occur in the course of time. which would render dynamite as dangerous as nitro-glycerine. The author recently made this objection to Mr. Nobel who, however, stated that there was no fear of such an occurrence, inasmuch as he had had dynamite in store for very lengthened periods, subject to high temperatures, and that it retained its original condition under some very trying tests. The stability of dynamite has been practically confirmed by extensive and daily use in various mines, and by the large quantities which are stored at the factories. Beyond this the most eareful investigation has shown that there is not the slightest ground for apprehension on that Under continued exposure to the direct rays of the sun during the whole of last summer, not the slightest chemical changes could be detected, and the same was the case with some dynamite exposed for forty days to a heat varying between 150deg, and 200deg. Fah. All nitrated. or rather hyponitrated organic compounds are liable to spontaneous decomposition—or what is understood by this backneved and ridiculous term unless they are completely rid of free adhering tric acid. The reason is that the free acid will nitri**c a**cid. produce a local decomposition, which sets hypo nitric acid free, the latter producing a new local decomposition, and so on until sufficient heat is evolved to set fire to the compound. is no difficulty whatever in ridding dynamite of free acid, but in the case of cotton or any other fibrous substance the utmost care is required, as free acid will sometimes adhere in spite of repeated washing.

In order to bring the matter down to the present time, it may be as well briefly to note the progress dynamite has made since the experiments at Merstham were carried out. In Germany, depots have been established in every mining district throughout the country, and the sale is rapidly spreading. In fact, there are but few mines in the north of Germany which are not more or less The danger attending the use of a shell was too north of Germany which are not more or less times the beaten track of our engineering predegreat to allow of its adoption by Mr. Nobel, but using it and if it has not as yet become as general as cessors, and exploring new fields wherein to exercise

gunpowder, it is owing only to the slow and sure system peculiar to the German race. The best proof, perhaps, of the great ascendency of dynamite in Germany is the circumstance that a firm at Cologne, who are the largest manufacturers of blasting powder in Western Prussia, have become converted to dynamite, and have taken up its agency. In Sweden, Mr. Nobel informed the author, that there was some difficulty in prevailing on the miners, who had become used to nytroglycerine, to use dynamite. But since the prohibition of the liquid explosive in that country, in September last, the sale of dynamite has been much larger than that of nytro-glycerine used to be. Sweden consumes at present nearly as much dynamite per month as Great Britain does in a year, which only proves the want of organization which has hitherto stopped its progress in this country. In Norway, the consumption of dynamite is not very large (from about 35,000 to 40,000lb. a-year, the author is informed), but it is steadily increasing. In California, dynamite is in great favour, and is transported by rail without any restriction. In the Eastern States of the American Union the miners still continue to use nitroglycorine, chiefly because dynamite has not been manufactured and sold there. In England, comparatively little dynamite has been used until This is owing to the difficulties of and to the fact that Mr. Nobel has transport, hitherto directed his attention to its manufacture and sale upon the Continent. There is but one There is but one depôt for the whole of Great Britain, and that is situated at Carnarvon. As, however, dynamite is not carried by rail, a great many orders are not executed. Still, the quarries of North Wales are regularly supplied, and consume a good quantity. Only three weeks since, a small cargo of ten tons of dynamite in cartridges was shipped from Hamburg to Carnaryon.

The author has referred to several catastrophes which have been caused by nitro-glycerine, but he can only find that a very few have resulted from dynamite. Since the latter material has been introduced, no accident has occurred either from its manufacture, conveyance, or storage. When the nitro-glycerine factory exploded at Stockholm last year, the dynamite stored close by was found scattered about, but not exploded. Two accidents have happened from the use of dynamite in mines. was caused by the tamping having been incautiously removed after a miss-fire—an operation which ought not to be allowed in any case. The second was due to the folly of lighting the fuse of a charged cartridge and holding it by the hand until it exploded. These are the only accidents the author can discover. Accidents like these, through carelessness, must and will occur in mines, however safe the explosive may be to handle.

It has been urged in some quarters that the addition of silica to nytro-glycerine constitutes a dead loss of explosive power. This, however, is a mistake. Practically speaking, there is no loss whatever. The dangerous properties of nitroglycerine, leakage into crevices, and subsequent untimely explosions under the miner's tools, render it absolutely necessary to make use of cartridges, which leave a considerable air room in the powder chamber of the bore hole. On the other hand, dynamite readily fills up the bore hole, and leaves no empty space. Practically, therefore, a bore hole charged with dynamite will hold fully as much nitro-glycerine as when it is charged with the liquid explosive oil, so that the silica is no drawback to its power, whilst it greatly enhances its safety, and renders it far more convenient for use.

(To be continued.)

### LONDON ASSOCIATION OF FOREMEN ENGINEERS.

T the monthly meeting of members of the A above association, held on Saturday, the 6th inst., the chair was occupied by Mr. Newton, of the Mint, president. Prior to the main business the evening, several new members were elected and proposed. Among the former was James M. Napier, Esq., of Lambeth, who con-tributed at the same time a donation of twenty guineas to the superannuation fund of the institu-

The paper read was entitled "The Epicycloidal Engine: an Effort to Effect Improved Screw Pro-pulsion." It was by Mr. Laird, who had also prepared diagrams and models for its illustration. The author, after demonstrating the necessity of leaving some-

our own inventive and constructive skill, remarked upon the defects of existing marine engines as used in screw propulsion. "The modern shortstroked horizontal screw engine," said Mr. Laird, "owes its shortcomings to the desire to pack the whole machine into the smallest possible compass. That engine, however, is the best which, with a given total length, has the longest connectinggiven total length, has the longest connecting-rod. The disadvantages of the short connecting-rod may be comprehended as thus:—lst. In-creased friction produced by the augmented rubbing pressure of the guide-pieces; 2nd, a certain amount of increased friction on the joint-in between the pieter and connecting and 3rd pin between the piston and connecting-rod; 3rd, increased friction at the crank shaft bearings due to the alternate lift and down pressure upon the shaft; 4th, and most important of all, perhaps, is the irregularity of motion induced by two violent pressures succeeding each other at short intervals, and the long pause intervening when the force is very small.
"In the epicycloidal engine two cylinders of

rather unusual length are placed on either side, and parallel to the screw shaft. To the ends of the piston-rods guide-blocks or slippers are keyed or otherwise secured. Two pins pass through the blocks, and these carry friction rollers with V edges. The rollers work into epicycloidal grooves, cut on the circumference of a barrel, and thus communicate to the latter a rotary motion. barrel communicates motion to the screw shaft and propeller. The object is to create on the face barrel such a curve as would give the action of the crank transmitted to the travel of the piston. In order to obtain this end the circum-ference of the barrel was divided into a given number of parts, say, 12, and half its length into 144, or the square of 12. Then, starting from the middle with 2 on the circumference, and drawing a line to 4 on the half length—from 3 to 9, 4 to 16, 5 to 25, and so on till reaching 12 to 144—a geometrical curve such as that seen on the model exhibited was obtained. The alternate action of the friction rollers into the grooves give the required rotary motion." The author of the paper then entered further into the peculiarities of the construction of the engine but probably its principle will be comprehended from the foregoing observations. In conclusion, Mr. Laird enumerated what he considered to be its practical advantages. They were as follow: Economy of steam, more steady and equable motion, reduced strain on the bearings, and consequently less friction, and, lastly, simplicity of mechanism. The merit of originating the idea of such an invention was due to Captain Ashe, R.N.

During the discussion which followed, Mr. Irvine remarked that he feared the rollers would wear very rapidly, and that he dreaded the evil of back lash. Mr. Stabler defended the crank from the attacks made upon it. Mr. Ives imagined that the friction rollers might be more advan-tageously applied than as shown in the model. Mr. Jansen considered the engine to be a modification of a similar contrivance invented by himself many years since. Other members objected to some one or other of the arrangements.

Mr. Laird having replied, the chairman, in putting the customary vote of thanks, remarked that it would be difficult for the author of the paper to have found a more practical or outspoken audience in the metropolis than he had met that night. He must not be discouraged, however, for it was the habit of foremen engineers to express their views on mechanical points with great freedom. Many inventors had had to run the gauntlet of criticism before their pet schemes had been received and adopted, and, for himself, Mr. Newton said he rather preferred that objections, conscientiously entertained, should be enunciated freely. They had all been instructed by the evening's proceedings, and Mr. Laird would probably think over the various theories, favourable and adverse, advanced during the sitting, and accept or dismiss them as might seem fit.

In closing the proceedings, the chairman expressed a hope that all the ordinary members would be present at the anniversacy festival on the 13th, and that their wives or sweethearts would grace the ladies' gallery with their presence on that occasion.

THE Belgian journals state that, in the neighbourhas beginn journals state that, in the neighbour-hood of Charleroi, a violent epidemic has broken out amongst the cats and dogs. These household pets die after suffering great agony for two or three days. The nature of the visitation has not been accurately ascertained.

# THE TEMPERATURE OF 1868.

AST year will long be remembered for the high temperatures which were registered, which will give an interest to the following statements by Mr. Glaisher, the President of the Meteoro-logical Society:—The mean temperature recorded at the Royal Observatory, Greenwich Park, was 37.2deg. in January, being 1.0deg. higher than the average of the preceding ninety-seven years; the average of the preceding ninety-seven years; in February, 43 Odeg., or 4 Gdeg. higher than the average; in March, 44 O, or 3 Ideg. higher; in April, 48 I, or 2 2 deg. higher; in May, 57 3, or 4 Sdeg. higher; in June, 62 O, or 3 Odeg. higher; in July, 67 5, or 6 Ideg. higher; in August, 63 6 or 2 Odeg. higher; in September, 60 5, or 4 Odeg. higher. The warm weather had prevailed from January 12 to September 30. On October 1 there was a change, and in October the mean there was a change, and in October the mean temperature was only 47.9, being 1.8deg, lower than the average; and in November 41.5, or 0.9deg, lower. On December 2 warmth returned, and the mean temperature of that month was 46.0, being 6.9deg. higher than the average. The mean of these monthly rates gives 51.55 for the mean temperature of the year. The temperature at the Observatory fell to 22-8deg. at the beginning of January, and was 96.6 on July 22, the highest temperature ever recorded at Greenwich. The range of temperature in the year, theretore, was 73.8deg.

# Correspondence.

PRESERVATION OF IRON SHIPS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I have just been shown your impression of January 29, which has an article on the above subject, containing the results of the "most recent and successful attempts in this direction," and find it stated that the "Urgent" troop-ship had been selected to try one of them on. The article relates that "After nearly two years' trial of the composition on that ship, it was found to be as clean as the first day it was put on, although in the meantime the 'Urgent' had been in all parts of the world." I read the above article with great doubt—in fact, with positive unbelief; and in looking through the "Standard" of to-day I find the following, which, as it has such an important bearing on the article in question. I send for your information:—" Urgent, '4, iron screw troop-ship, Captain S. Henderson, at Devonport, has been taken into dock to have her bottom cleaned." The italies are mine, and this statement gives additional proof of the correctness of my remarks and statements in my work on the "Fouling and Corrosion of Iron Ships," that no componity helps. and statements in my work on the "Fouling and Corrosion of Iron Ships," that no compo, paint, glue, plaster, powder, putty, pickle, or other similar contrivance, is of the slightest use whatever, except as a very temporary expedient, for either keeping an iron vessel clean, or the hull free from corrosion, longer than two orthree months at a from corrosion, longer than two orthree months at a trom corrosion, longer than two orthree months at a time, after which it requires to be "hogged," and the vessel docked, with all attendant expense, loss of time, &c., and be repainted, plastered, or smeared, as before, shortly after.—I am, Sir, yours, &c., CHARLES F. T. YOUNG, 7, Duke-street, C.E., M.S.E., Assoc. I.N.A. Adelphi, W.C., February 8.

THE directors of the East London and South The directors of the East London and South London Junction Railway, in their report just issued, state that they confidently expect the first section of the line—from New Cross to Wapping, via the Thames Tunnel—to be ready for opening for traffic in May. Mr. Hawkshaw, the engineer, reports that the works on the south side of the river are in a very forward state, and the contractors have given an assurance in writing that, saving unforeseen difficulties, the line shall be completed to Wapping by that time. The directors home shortly to compute the second The directors hope shortly to commence the second or northern section of the line, from Wapping to the lines running from Fenchurch-street and Bishopsgate stations.

The Manufacture of Watches and Clocks.

A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progross of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, who holds the appointment to the Prince of Wales, sends this pamphlet to any address on receipt of two postage stamps, and we cannot too strongly recommend it to the notice of the intending purchaser.—| Advr. |

### TO CORRESPONDENTS

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 is. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

advance.
All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 50 clock on Thursday evening.
We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith, ED. M. M.
Advertisements are inserted in the MEGHANICS' MAGAZINE.

faith, ED, M. M.

Advertisements are inserted in the MRCHARIGS MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists
of about 10 words. Woodcuts are charged at the same rate
as type; Special arrangements made for large advertisements.

# Nabal, Military, and Gunnery Items.

It is stated that the effect of the reductions in the Army Medical Staff will be so large that no fresh admissions to the service are likely to take place for a year, if not longer.

A STRIKE of the sailors of all nationalities in New York for higher wages is reported. They now get 16 dollars a month, their wages having lately been reduced, and demand 30 dollars.

We note with satisfaction that the King of Italy has conferred the decoration of the Italian crown, with the grade of Chevalier, upon Mr. Henry Lumley, the inventor of the Lumley rudder.

WE understand that the Commissariat Department of the Army will cease to exist as a separate establishment after the 1st April. Thirty of the present staff of officers are placed on half-pay from this day.

According to the "Bureau Veritas," of Paris, the number of vessels totally lost during the year 1868 was 2.371, of which 2.261 were sailing vessels and 110 steamers. The number of total losses in 1866 was 2,932, and in 1867 3.045. Of the vessels lost in 1868 no less than 1,122 bore the British flag, 253 were American, 210 French, 203 North German, 103 Dutch, 71 Norwegian, and 50 Italian.

WE read that there is no truth in the report that the "Victory" is to be dismantled and removed from her present moorings to the ordinary in Portsmouth harbour. The only change to be made will be that harbour. The only change to be made will be that she will no longer carry the flag of the Commander-in-Chief, or have the flagship's crew and staff on board of her. She will be open to the inspection of visitors as before, and her fittings will be undisturbed.

The new screw steamer, "City of Brooklyn,' built by Messrs. Todd and M'Gregor, of Glasgow. for the Liverpool, New York, and Philadelphia Steam Ship Company, arrived in the Mersey, a few days since, from the Clyde. She is 2,911 tons, customs new measurement, with engines which worked to upwards of 2,300-horse power on the ru round from the Clyde. The run from the Clock to the Cumbraes, with the wind on the port bow, was made in 59 minutes and a half, being at the rate of

building yard, conducted by private enterprise With respect to Deptford yard, which ordinarily employed about 750 hands, it is proposed that model workshops should be established in it—a portion being allotted to the use of manufacturing firms who would become tenants of the Government.

The annual meeting of the Marine Society was held yesterday week, at the offices in Bishopsgate-spreet; the Right Hon. the Earl of Romney, president, in the chair. The report of the Committee for the past year was read and adopted. By this report it appeared that during the twelve months ending 31st December, 1868, 308 poor boys had been received on board the society's training ship "Warspite," at Woolwich, of whom 97 had been sent into the Royal navy, and 187 to the merchant service. The complement of boys on board the "Warspite" had been kept up at 150 (this has since been increased to 160). The committee earnestly invited the attention of all benevolent persons to the good which is being effected by the Marine Society in receiving so many hundreds of destitute boys, and training them for employment a the sea service.

His Excellency the Governor-General of India in Council has much satisfaction in publishing in the "Gazette of India," for general information, the following paragraph of a military letter from the Right Hon. the Secretary of State for India, No. 420, dated the 4th December, 1868:—"Paragraph 1.—I have much pleasure in acquainting your Excellency, that Her Majesty has been graciously pleased to signify her pleasure that a medal be granted to all Her Majesty's British and India forces, naval and military, who took part in the operations in Abyssinia which resulted in the capture of Magdala." The Governments of Fort St. George and Bombay, and his Excellency the Commander-in-Chief in India are requested to adopt early measures for furnishing the rolls of the officers and soldiers or corps who are entitled to the medal now authorized by Her Majesty.

A WROUGHT-IRON pier designed by Mr. C. E. Grover, for the contractors of the work, Messrs. Loutith and Sharrock, of Liverpool, is now in course of construction opposite the Royal Gun Factory Department Royal Arsenal, Woolwich. The pier is to rest upon iron columns, and operations were commenced this day week to screw the first cylinder of No. 1 pier into the bed of the river. The iron used throughout, of which the pier will be constructed, has been tested by the War Department, with the following satisfactory results:—T-iron average breaking strain, 24-50 tons per square inch, and ·158 elongation; angles and bars 21-25 per square inch, and ·158 elongation; plates in girders and wroughtiron cylinders, 24-31 per square inch, and ·158 elongation.

The "Swallow," gunboat, lately made a trial of her engines at the measured mile in Stokes Bay. Her engines are by Messrs. J. Rennie and Son, with Griffith's screw; the draught of water forward is 8ft. 8in., and aft 10ft. 1in.; the load on safety valve, 30lb. Six runs were made at full boiler power, realising a speed of 11·017 knots per hour; and four runs at half boiler power, realising 9·361 knots per hour. Eight circles were made with the following results:

—Both engines ahead, starboard, 3min. 29sec.; port, 3min. 30sec.; one engine ahead and one astern, starboard, 3min. 37sec.; port, 3min. 38sec.; with the vessel at rest, all helm, and one engine only—starboard, 4min. 23sec.; port, 4min. 30sec.; ditto, without the helm, and one engine only—starboard, 6min. 25sec.; port, 6min. 26sec.

The loss of Venetia has not in the least diminished the effective force of the Austrian commercial marine; on the contrary, it is greater now than it was in 1865, when the province still formed part of the empire. In that year its strength was 3,441 vessels of 324,804 tons. At present it does not count more than 3,221, being 220 less, but in the tonnage has advanced to 330,586. The diminution in number has occurred exclusively in the coasters, but in vessels making leng voyages there is an augmentation of 10, and an increased tonnage of 10,173. In comparing the statistics of the sailing vessels in 1868 with those of 1867, there is a difference to the advantage of the former of 569, 19,587 tons, and 762 sailors. The Austrian merchant navy for last year, steamers included, comprised 7,963 of 343,030 tons, and 15,611 horse power, manned by 27,387 seamen.

# Miscellanen.

In four adjoining tenements at St. Buryan, in the Land's-end district, there are living nine persons, whose average ages somewhat exceed 74 years.

THE "Gazette des Hopitaux" announces that subnitrate of bismuth has been employed in large doses with wonderful success in Algeria as a specific for dysentery.

A FEW days since the electric fluid fell on the church of the commune of Fougerets, Bretagne, when the steeple and a portion of the building became the prey of the flames.

THE sixteenth anniversary dinner of the London Association of Foremen Engineers is appointed to take place to-morrow, the 13th instant, at the City Terminus Hotel" (Cannon street Station.)

RECENTLY Mr. Gristwood, of Clewer Court Farm, near Windsor, caught in a net, at one haul in the Thames, 400lb. of pike, perch, and other fish. Mr. Gristwood has a right to use a net to the extent of his boundary.

THE three oxen for the promenade of the boungras at Paris were this year purchased by dealers unconnected with the butchery trade, who paid £760 for them, an enormous sum, amounting to 3s. 4d. for the pound of meat.

WE are informed that the College of Physicians has ordered the printing of a number of copies of the "New Nomenclature of Disease." The work will be on sale at the college in Pall-mall in about a week or so.

THE amounts at the credit of savings banks with the National Debt Commissioners on January 23, were as follows:—Trustee savings banks, £36,867,634; Post Office savings banks, £11,811,042, making a total of £48,678,676.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending February 6, 5,094. Total number since the opening of the Museum, free daily (May 12, 1858), 1,497,751.

Through the upsetting of an engine on the railway, the telegraph wires of the Mediterranean line were recently broken. Communication was cut off for three or four days, as they never repair anything in a hurry in Spain.

THE tower of the parish church of St. Issey, Cornwall, which contained a fine peal of bells, fell with a tremendous crash on Tuesday week. The roof of the church was broken entirely in, and the organ was smashed to pieces. The heavy gales have gradually brought about this destruction.

THE number of Cornish pumping-engines reported for December is 20. They have consumed 2,158 tons of coal, and lifted 16-7 million tons of water 10 fathoms high. The average duty of the whole is, therefore, 52,300,000lb., lifted 1ft. high, by the consumption of 112lb. of coal.

EARLY on Sunday morning, Florence was visited with two shocks of earthquake. They were, fortunately, slight, and did no damage beyond causing a good deal of alarm to the inhabitants by the shaking of the furniture and the moveables in the houses.

At Trebarwith Downs, in the parish of Tintagel, Cornwall, a slate quarry has been recently opened, under the superintendence of Captain Jenkins. Recently, a workman split a large piece of rock, in which he found embedded the fossil of a reptile about 20in. long. This stone was raised 22ft. from the surface, or 17ft. in solid rock.

The time gun at Newcastle, very much to the surprise of the town, went off at five minutes to twelve on Saturday morning. The attendant had loaded the gun an hour before his usual time—namely, at half-past eleven, instead of half-past twelve, and the electric telegraph officials had happened shortly afterwards to test the wire; hence the unusual report. The gun was fired again, as usual, at one o'clock.

THE number of visitors to the South Kensington Museum during the week ending February 6, 1869, was—on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 14,828; Meyrick and other galleries, 3,024; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,810; Meyrick and other galleries, 210; total—19,872. Average of corresponding week in former years, 9,768. Total from opening of Museum—8,136,767.

The following is a return of the quantity of coal exported from Grimsby during the month of January:—To Belgium, 676 tons; Denmark, 636; Egypt, 6,158; France, 5,785; Hanseatic Towns, 1,112; Holland, 346; Italy, 2,254; Norway, 167; Spain, 1,730; Spanish West Indian Islands, 777. Foreign, 19,641 tons; corresponding period, 1868, 19,640 tons. Coastwise, 2,506 tons; corresponding period, 1868, 4,821 tons. Total, 22,147 tons; corresponding period in 1868, 24,461 tons. Decrease, 1869, 2,314 tons.

A TERRIBLE storm broke over Bragneres de Luchon, France, a few days ago. Its fury was such that many of the farmhouses and barns in the valleys of the Lys and the Hospice are demolished or damaged. In the village of Saint Mamot all the thatched roofs and many slated ones were blown off. Several enormous elms and poplars have been uprooted. Towards ten at night a column of flame indicated that the forest of Cazarith was on fire, and the strength of the wind caused the conflagration to spread rapidly.

THE emigration returns for the Clyde ports during the past month show a very large decrease over those of the corresponding month in 1868. In January, 1868, 618 emigrants left the Clyde; but in £180.

January, 1869, only 352. In the month of January, in 1867, 1866, and 1865, the numbers were respectively 240, 402, and 233. Of the emigrants who embarked last month all went to America save one, who sailed for Palermo. New York alone absorbed 336, Portland 10, and Demerara 5. Of the passenger arrivals during the month there were 210, all from New York.

HEATING churches by hot water would appear to be not entirely unattended by danger. The church of Restalrig, N.B., a quaint old-fashioned looking building—a restoration of an edifice which dates from the time of James III.—has for some time past been heated by steam. The furnace is under the charge of an old woman and a boy, and it was lighted as usual on Sunday week. It is supposed that, from inattention or want of knowledge, it had been allowed to get overheated; and about twelve o'clock the pipes burst, with a report described as being equal to the noise of a battery of field pieces. One gentleman had his arm severely scalded. The damage done to the church is very considerable.

The Royal Horticultural Society held their annual general meeting in the council-room at South Kensington on Tuesday last, Mr. J. Bateman, F.R.S., in the chair, when three new members of council were elected—viz., his Serene Highness the Prince Teck, Lord Londesborough, and the Rev. Joshua Dix. The report was then read by Mr. Richards, the assistant secretary. Mr. Dale proposed, and Mr. Plumbe seconded, the adoption of the same, which was carried. Mr. Edgar Bowring, C.B., M.P., proposed a vote of thanks to the chairman, not only for his conduct in the chair on that occasion, but also for the many interesting lectures he had been good enough to favour the society with during the past year; and to the council generally for their excellent management of the affairs of the society.

THE great ploughing match, which is perhaps the most important this season, has just come off at Rudchester, near Newcastle-on-Tyne, and was one of the most successful the Northumberland Society has ever held. The greatest excitement prevailed, competitors attending from long distances, and ne less than 60 teams entered the lists. All the prizes in the Men's Swing Plough Class were carried off by local ploughmen, with Howard's ploughs. Messra. Howard had presented a wheel plough to be competed for in the wheel class, and this was won by a local ploughman with a Hornsby's plough, completely distancing Messrs. Ransomes, whose ploughs, it is stated, were beaten in every class by Howard's or Hornsby's, very different results to those obtained by Ransomes ploughs in Durham.

The Brazil Mint, at Rio Janeiro, is under the direction of the Minister of France. The governor is called the provedor. The steam machinery and pipes for casting and coining, &c., are of the most perfect kind. In the assay of gold, 200 milligrammes are now employed. The refining is carried on in plantinum vessels. From July, 1840, to July, 1864, says the "Society of Arts Journal," there were struck 38,808,890 gold coins, and 13,765,553,500 silver, besides many medals of various kinds. There is in the mint a collection of the various coins struck in the former monetary establishments of the country, and 572 coins of other countries. It has also 83 dies of Brazilian medals, and 1,027 foreign medals. There is attached to the mint a school for painting, plaster-sculpture, and engraving, and each workshop has its own library.

The excavations of the Temple of Bacchus at Athens are just now attracting the attention of antiquaries. M. Piot, a French gentleman, writes from that city that he has just discovered the remains (trunk and head) of a colossal faun. What renders this discovery the more interesting is that M. de Longperier, after esmparison of the measures given by M. Piot, has found that the proportions and forms of the faun are just those of the four caryatides in the Louvre. These last were known to come from the Villa Albani, but the place of their first origin had not been ascertained; the fifth is at the nuseum at Stockholm. There is now every reason to suppose that it is the sixth of these statues which has now been discovered, and that it formed, with others, the monumental decoration of the Athenian Theatre consecrated to Bacchus.

The organization of efficiently constituted fire brigades has been a matter of serious consideration amongst many of the authorities in our country towns. Amongst those towns may be selected Market Rasen and Wragby, in Lincolnshire, and Wootton Basset, near Swindon. These towns, each averaging a population varying from 3,000 to 5,000 inhabitants, have selected, through their committees appointed for the purpose, the well-known "Paxton" fire engines introduced by Messrs. Merryweather and Sons, in the year of the Great Exhibition, 1851. This description of engine was designed by the above firm to meet the requirements of the country towns, both as regards simplicity, easy management, and cost. It is stated that the fire brigades in each of the towns are fully equipped with fire-engine and every requisite for sums varying from £105 to

# Watents for Inbentions.

# ABRIDGED SPECIFICATIONS OF PATENTS

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. I should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are bereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2336, 2346
BUILDINGS AND BUILDING MATERIALS—2299, 2307, 2324,

2345
CREMISTRY AND PHOTOGRAPHY—None
CULTIVATION OF THE SOIL, including agricultural implements and machines—2311, 2341
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c. —2302, 2304, 2312, 2315, 2327, 2331, 2338, 2339, 2344

1339, 2344
FOOD AND BEVERAGES, including the apparatus for pre-paring food for men and animals—2329
FURNITURE AND APPARKL, including household utensils, time-keepers, jewellery, musical instruments, &c.—

time-keepers, jewellery, musical instruments, &c.—
None.

2298 An extension of time for filing the specification of this patent has been granted by order of the Lord Chancellor, on account of opposition having been entered against it.

cellor, on account of opposition having been entered against it.

2299 W. T. Hamilton, Dublin. Dove-lailing machine.
Dated July 22, 1868.

The principle of this machine is this. A disc carrying a circular saw is mounted upon an axie capable of reciprocating as it rotates in its bearings. The movement of this disc is so governed, that the saw shall be always in a vertical plane, and, by its sweep, cut away the material offered to it in a triangular form. The mounting of the disc is upon the principle of a universal joint, the inner member of which is free to turn upon a pin passing through the axie, whilst the disc or outer member is free to turn upon a like pin passing through the inner member. These pins are at right angles to each other, but in the same plane. The disc, and with it the saw, is thus free to move in every direction, but a rim or strap working on the circumference or side of the disc maintains them always in a vertical plane, either by turning upon two pivots provided in the frame, one above and the other below the saw, or by working in a horizontal slot at the back of the saw. When the material is passed up the front of the saw vertically, a tail will be cut, When the material is advanced endwise or horizontally upon the saw, the interval between two pins will be cut, the circuiar effect of the saw being rectified by a small vertical movement of the feeding table.—Patent completed.

2300 C. F. Waldo, Cheapside. Raising water. (A communication). Dated July 22, 1868.

table.—Patent completed.

2300 C. F. WALDO, Cheapside. Raising water. (A communication). Dated July 22, 1868.

This consists in obtaining vacuum by the sudden condensation of steam. By this invention, by means of the sudden condensation of steam, an instantaneous vacuum of far greater comparative proportions is obtained than usual, into which the water or fluid, almost as instantaneously, is drawn, and is then expelled therefrom, simply by the force of steam pressure, directly applied, so that by the alternate application of the suction power of a vacuum caused by the condensation of steam in a vacuum chamber, whereby such chamber is caused to be filled with water or fluid, and the direct application of the power of steam pressure to the water or fluid to expel it therefrom, the water or fluid is transferred from one elevation or place to another.—Patent abandoned.

2301 W. T. HAMLITON. Dublin. Converting motions.

another.—Patent abandoned.

2301 W. T. HAMILTON, Dublin. Converting motions.
Dated July 22, 1868.

An axle is so mounted as to be free to revolve and reciprocate in its bearings. A circular disc is mounted on this axle as to be inclined to its at my desired angle. The disc revolves in a rim or ring in the nature of an eccentric strap. This strap carries a pin, which works in a hole in a vertical stud, and is so mounted in the frame of the machine as to be free to revolve through a small arc. The pin has thus a freedom for radial as well as for twisting motion. To obtain reciprocation without rotation, the axle is made merely to revolve, whilst the object in which the vertical stud is mounted is left free to move in guides. Or the vertical stud may remain fixed, and the axle free, whilst a second pin is introduced at the opposite side of the strap working in a second vertical stud. The object in which this last is mounted will then reciprocate.—Patent completed. completed.

2302 L. DULAC, Le Nord, France. Drying threads. Dated

2302 L. DULAC, Le Nord, France. Drying threads. Dated July 22, 1868.

This relates to improved machinery or apparatus for effecting the simultaneous drying and beating of flax, hemp, cotton, wool, and other threads or hanks. The machine is composed of a central horizontal shaft, carrying circular plates or discs, from which radiate a number of arms. Each disc carries an equal number of arms, on which latter are placed other bars in a parallel position to the shaft. These bars form a series of pallets, corresponding in number to the arms around the central shaft, leaving an open space between them and the shaft. The shaft is

mounted at each end in a framing, forming air chambers in communication with the centre of the machine. There are four modes ordinarily employed in drying threads:—First, by centrifugal force; second, by a vacuum or rarefaction of the air; third, by a current of air; fourth, by theat. The whole of these are combined in the machinery of this invention. Thus the centrifugal force produced by the rotation of the machine will discharge the moisture from the centre towards the circumference. The air also being by the centrifugal force driven towards the circumference, will further serve to produce the rarefaction suited for extracting the moisture. This rarefaction may be increased or diminished by means of doors, the opening of which is regulated according to the amount of air to be admitted into the chambers.—Patent completed. mounted at each end in a framing, forming air chambers in communication with the centre of the machine. There

which is regulated according to the amount of air to be admitted into the chambers.—Patent completed.

2303 S. H. Hadler, Hampstead. Decorticating grain. Dated July 22, 1868.

The patentee proposes to employ a box, into which the wheat or grain is fed, and in which it is subjected to a rubbing action; this box is open at the top and closed at the bottom. Inside the case, and extending down to the bottom thereof, is a revolving agitator or rubber, which may be of a conical or other form; the wheat or other grain to be decorticated is fed freely and continuously into the top of the box, so that the box is kept full of grain, and the grain passing down between the sides of the agitator or rubber and the case is thereby subjected to a rubbing action, and is allowed to escape through holes in the side of the box and near its bottom, or through openings in the bottom itself. The size of these openings may be regulated by slides, so as to regulate the speed at which the grain passes through the machine, and consequently the amount of friction to which the grain is subjected, the space between the bottom of the central agitator or rubber and the side of the box is, by preference, made less than the space between the top of the agitator or rubber and the box; the surfaces, both of the central rubber and the box, are also, by preference, corrugated; the central rubber as caused to revolve rapidly, and the outer box might be made to revolve slowly in the same direction.— Patent completed.

2304 T. A. WARD and H. WHALE, Newington-causeway. Racket bats. Dated July 22, 1868.

The hoop of the racket bat is made of cane, instead of sah, as now used, with a plece of hard wood glued down the centre of the handle to give it solidity; the bat is strung with gut in the usual way.—Patent abandoned.

2305 C. E. BROOMAN, Fleet-street. Firearms. (A communication). Dated July 22, 1888.
This invention relates to breech-loading firearms of that class in which the breech end of the berrel is closed

2305 C. E. BROOMAN, Fleet-street. Firearms. (A communication). Dated July 22, 1868.

This invention relates to breech-loading firearms of that class in which the breech end of the barrel is closed by a block, whose rear end works on a horizontal pin having its axis at right angles to the axis of the bore of the barrel, and consists in a peculiar combination of mechanism, whereby the arm is made stronger, more easy to operate, simpler in construction, and more economical to manufacture, than other firearms of its class.—Patent completed.

2306 T. F., J. F., C. H., and E. FRITH, York. Looms. Dated July 22, 1868.

These improvements have especial reference to hand looms and power looms used in the weaving of carpets, or to woollen, worsted, or other fabrics, and consist of a simplified arrangement of parts whereby pieces are woven in which considerable variation of the "shed" is required to obtain the requisite pattern or design. For this purpose, two treadles or levers are employed, each of which communicates, by means of an overhead lever, with an arrangement of mechanism as follows:—Above the loom and over the healds a small framework is mounted, provided with a horizontal "cart cylinder" on either side. Between each cylinder and the framework hang a series of vertical metal plates or strips, it yields inwards or towards the framework, and so presses a horizontal pin (having an oblong late in its centre part) through which any one of the metal plates or strips, it yields inwards or towards the framework, and so presses a horizontal pin (having an oblong lot in its centre part) through which passes a vertical flattened needle or "tabbie," the lower end of which is connected by a cord passing over a pulley swinging from the top of the framework to an adjoining needle or tabbie and consequent heald. On either side of the two rows of needles connected as before-named to their relative healds, passes a horizontal lever, having its fulcrum in the front part or side of the loom, and connected with the treadle lever ar

-Patent completed.

2307 H. Fear, Birmingham. Door springs. Dated
July 22, 1868.

At the lower part of the axis on which the door turns is
a double incline, and a roller carried by a vertical slide
bears upon the said double incline. On the top of the slide
a series of flat springs press, the tension of which may be
increased or diminished by means of a screw acting upon
them near their fixed ends. When the door is opened, in
one or other direction, one or other of the inclines

described raises the roller and slide, thereby bringing the flat springs into action, and when the door is at liberty to move, the pressure of the roller on the incline brings the door to its closed position.—Patent abandoned.

door to its closed position.—Patent abandoned.

2308 F. H. Hambleton, Piccadilly. Armour plates.
Dated July 22, 1868.
Several plates or bars of which a forging is to be composed are heated by suspending them vertically in a furnace, the plates being suspended at such a distance apart from one another as to allow the heat to have free and uniform access to the entire surface to be welded. Subsequently, the several plates or bars are welded by drawing them up vertically through rolls. By thus keeping the plates or bars in a vertical position whilst they are passing through the rolls, perfect facilities are afforded for the escape of all impurities from the surfaces of the several plates of metal as they together come up to the rolls. The rolls may be placed over the mouth of the furnace, so that the plates may be drawn up vertically from the furnace through the rolls. Or if plates be placed on edge horizontally in the furnace, a suitable distance apart, the plates might be drawn horizontally from the furnace, then turned on end, and afterwards welded together by being drawn up vertically through rolls.—Patent completed.

2309 W. DENNIS, Aldermanbury. Letter boxes. Dated

drawn up vertically through rolls.—Patent completed.

2309 W. Dennis, Aldermanbury. Letter boxes. Dated July 22, 1868.

This consists in constructing the box with or without a fan wheel at the aperture, and dividing the box, at about the centre thereof, with two pieces of metal of a triangular form, somewhat similar to the letter V, and either with or without a flap joint near the point thereof. The flap joint may be shut by a hinge, and made to balance and close of itself after a letter in its descent has pushed it open, and passed through into the bottom of the box. In constructing letter pillars according to this invention, a bag is employed having iron rims similar to a travelling bag, and fitted with one or more spring locks. The pillar is fitted with two doors; upon opening the first or outer door, a handle must be pulled before the inner door can be opened. This handle is fixed upon a metal rod formed with a projection at the end, which pulls the two rims of the bag together, so as to lock the bag. This movement serves also to release the lock of the inner door, so that it can be opened and the bag with letters taken out and locked. A key is to be kept at the chief office for opening the bag.—Patent abandoned.

2310 J. Bowron and G. Lunge, South Shields. Iron

the bag.—Patent abandoned.

2310 J. Rowron and G. Lunge, South Shields. Iron and steel. Dated July 23, 1868.

This consists in mixing fluoride of calcium, the same being obtained artificially or in the form of native fluor spar, or the mineral known as "cryolite," either in a state of fine division or otherwise, with the materials used in blast furnaces, for the purpose of removing, either whollly or in part, the phosphorus contained in the pig iron to be obtained therefrom. The fluoride of calcium should be used in the proportion of from two to twenty times that of the phosphorus contained in the materials under treatment, according to the quantity of the latter, and the degree of purity which it is desired to produce. It further consists in using fluoride of calcium or cryolite in puddling and other furnaces as a "fetting," to aid in the manufacture of wrought iron and steel, by the removal of the phosphorus contained therein.—Patent completed.

2311 A. BRECHAN, Aberdeen. Ploughs. Dated July 23,

2311 A. BEECHAN, Aberdeen. Ploughs. Dated July 23, 1868.

The frame of the plough is similar in shape to those ordinarily in use, but is constructed in a lighter manner, and the mould board is also of the usual form. The sole of the plough is reduced very much in length, say, to fin, or thoreabouts. Immediately behind the sole is a wheel mounted in suitable bearings, attached to the frame, so as to run vertically. Behind this wheel is a smaller wheel also mounted in suitable bearings attached to the frame, but so as to revolve horizontally. The larger vertical wheel carries the weight of the plough and removes the friction of the sole on the ground, whilst the horizontal wheel takes the place of the side plate in the ordinary plough, and by its horizontal revolution on the groundut by the plough, the lateral friction is materially reduced.—Patent abandoned.

2312 E. T. Hughes, Chancery-lane. Treating flax. (A

cut by the plough, the lateral friction is materially reduced.—Patent abandoned.

2312 E. T. Hughes, Chancery-lane. Treating fax. (A communication). Dated July 23, 1868.

The object of this invention is to remove the glutinous matters enveloping the primary or cell fibres of flax, so that they can be more readily separated from each other by picking, carding, or other suitable machinery. A skeleton cylinder is placed within a tank which holds the chemical solutions. The cylinder contains the flax and is slowly rotated, the lower half of the cylinder being immersed in the different solutions, while the upper half is above and out of the same. This secures a thorough circulation of the solution, as gravity drains off the solutions from the upper half of the cylinder constantly immerses the lower half of the same. A longitudinal open space is made in the centre of the cylinder immediately around the shaft of lift, or lish, in diameter, as an escape for the solutions for the upper half of the cylinder. This space will also answer the purpose of introducing an air blast through the flax to dry it and to aid in the disintegration of the fibre at the close of the process. This open space is surrounded with longitudinal slat work to keep the flax in the body of the cylinder from filling it. The heads or ends of the cylinder except this open space, are closed. The cylinder except this open space, are closed. The cylinder emorable pieces are fitted on each section for filling and emptying the sections.—Patent completed.

2312 W. Gilbert, Birmingham. Lockets. Dated July 23

2313 W. GILBERT, Birmingham. Lockets. Dated July 23

1868.

The frame for carrying the miniature turns out of the case of the locket at the side of the case, instead of making the locket open by a lid similar to the lid of a box or cover of a book. The case is made of one piece of metal folded at its middle, the blank having the figure of the two sides of the case joined together by a narrow strip or band. The doubling of the blank is effected at the narrow strip or band. The frame of the locket may be composed of a blank having the figure of the two sides of the frame joined by a band or strip at the middle. When doubled at the band, the frame is fixed in the case by means of the suspending ring, which passes through a hole in the case and frame opposite, or nearly opposite, the bands where they are folded. The frame of the locket turns upon the suspending ring as a centre. The folded band of the case constitutes a stop against which the folded band of the

frame shuts or abuts, and by which the motion of the said frame is limited. The folded part of the frame also constitutes a catch, by means of which the frame may be drawn out of its case by the application of the thumb or fluger nail.—Patent completed.

2314 P. PEARSON, Leeds, Cocoa. Dated July 28, 1868,

1814 P. PEARSON, Leeds, Cocoa. Dated July 28, 1869,

1815 Cocoa nuts or nibs, obtained by decoction, infusion, or other known means, and adds thereto about one quarter of a pound (more or less, as desired), of cocoa from which the fatty matter has been wholly or in part previously expressed or extracted, and then adds (if desired) any suitable flavouring matter (such as vanilla, for instance), and also a sufficient quantity of alcohol or other preservative agent. By these means a concentrated essence or preparation of cocoa is produced in a liquid or semi-liquid form, and which is always ready for instant use.—Patent completed.

and which is always ready for instant use.—Patent completed.

2315 T. Hart, Blackburn. Cord and twine. Dated July 23, 1863.

This invention consists in the employment of a carriage and tramway. On the carriage, and parallel to the tramway, are a number of spindles carrying bobbins on which is the material or strands. At right angles to the tramway, or extending in front of the carriage, is a bar or rod having a number of holes or eyes therein, through which the strands are passed and attached to the "twisting frame." At intervals along the line of tramway are received a number of "stakes" or beaters having arms thereon extending across the tramway below or clear of the rod above mentioned, so that as the carriage passes along the tramway, the strands are deposited in notches of the bearing arms. The carriage having arrived at the end of the tramway, the eye rod is, by means of a rack and pinion on the end of the rod, caused to revolve, so that the strands are wrapped around such rod, and the carriage can thus be drawn towards the twisting frame and the twine put in. Attached to and working on the stakes or bearers, is an arm having angular indentations therein; this arm extends under the strands, and by means of a lever and wire, or cord, cau be raised by the attendant at the twisting frame, so that two or more strands may be raised out of the notches of the first arm to the angular indentations in the second arm, and doubled.—Patent abandoned. abandoned.

2316 F. HORNER, Manchester. Coating metals. Dated July 23, 1868.

July 23, 1868.

The improvements consist in the application of copper to the exterior surface of an inferior or base metal. For example, a chandelier now made of brass may be made of cast iron, and a coating of copper may be applied thereto by means of electrotyping apparatus.—Patent abandoned.

to the exterior surface of an interior or base metal. For example, a chandelier now made of brass may be made of cast fron, and a coating of copper may be applied thereto by means of electrotyping apparatus.—Patent abandoned.

2317 W. S. Harrison, Peckham. Timekeepers. Dated July 23, 1868.

The object of this invention is to enable a motor or regulator clock which keeps true or normal time to correct or regulate any convenient number of other clocks or timekeepers at a distance therefrom by means of a current of electricity which is caused to pass during the last few seconds of each hour (or at any convenient time) from the "motor" or regulator to the other clocks, detaching the motion work of the hands from the "going" mechanism, and unlocking the fly of a special movement which sets the hour, minute, and second hands backwards or forwards to the exact time required, holding them in that position until the moment that the motor or regulator roldicates the precise completion of the time, when the latter breaks electrical contact, unlocking all the hands of the other clocks simultaneously, and throwing them instantly into gear with the "going" mechanism, so that the starting of all the clocks at the time required shall be synchronous, and in perfect accordance with the time indicated by the motor or regulator clock. The arrangement of mechanism employed for effecting this object is as follows:

—The motor or regulator clock is provided with a pin or cam on the minute wheel, which, during the last five seconds in each hour, presses on a spring lever, and thus makes and maintains electrical contact with a battery connected therewith, and with a special "line wire" connected with all the clocks to be regulated, and thereby excites a magnet connected with each clock to be required. The movement of the armature raises a lever and releases a "fly," allowing the special setting mechanism to come into operation; this mechanism or train first disconnects the dial wheels and hands from the driving mechanism of the clock b

ously with the motor clock.—Patent completed.

2318 M. T. SHAW and T. H. TURNER, Cannon-street,
Hydraulic lift. Dated July 23, 1868.

This invention has for its object improvements in
hydraulic apparatus for lifting, hauling, and lowering, and
the improvements relate, first, to obtaining variations of
power from the hydraulic cylinder or cylinders of the lifting, hauling, or lowering apparatus. For two powers an
ordinary cylinder and ram is employed, the area of the
ram being as much less than the area of the cylinder as
the difference between the high and low power. This
ram is made sufficiently short so that another piston is
omployed that flis the cylinder water-tight, by packing or
other means, and which would, when the ram was at the
in part of the stroke, be at the bottom of the cylinder,
between the end of the ram and bottom cylinder cover.

There are two admission pipes at the top and bottom end of the cylinder, so that the water is admitted under the small ram, leaving the piston at the bottom of the cylinder, and exhausting only the central contents of the ram in the return stroke by the pipe at the top end and valve arrangement. When the high power is required, the patentees put the water under the loose piston, which then carries up the ram with it by simply pushing it—thus a second power is produced. In constructing turning gear for hydraulic cranes, a midfal piston of the requisite size is fastened on the main pillar of the crane, and revolving with it; this piston or plate is enclosed in an annular cylinder concentric with the main spindle, and, by means of a fixed partition standing out from the cylinder, passing across the annular space between the cylinder and the spindle, and also by valves or openings on either side of this partition.—Patent completed.

2419 J. PURDBY, Oxford-street. \*Pirearms.\* Dated July

2419 J. PURDEY, Oxford-street. Firearms. Dated July

23. 1882.
This invention relates to the obtaining for firearms a movable and adjustable elevator for the breech, to suit the varying requirements of the user. Over the tang of the breech-piece a removable plate is filted, corresponding in shape somewhat with the shape of the tang of the breech-piece of the firearm. This plate is secured in place on the tang by hooking its rear end into a slot cut in the tang of the breech-piece, but it may be secured in any other convenient manner that will allow of its being readily unshipped and removed. The height or vertical position or elevation of the forward end of the movable plate is regulated and adjusted by means of an adjusting screw, which enters a hole tapped in the tang.—Patent completed.

2320 C. E. BROOMAN, Fleet-street, City. Rolary angines.

which enters a noise tapped in the thing.—ratent completed.

2320 C. E. Brioman, Fleet-street, City. Rolary engines.
(A communication.) Dated July 23, 1868.

This consists in a new arrangement of rotary steam engines, in which the steam acts by reaction on hollow radii disposed in a special manner, which reaction produces a rotary motion in the contrary sense to the escape of the steam. The machine is composed as follows:—A movable cylinder or disc is mounted ou a hollow axle. This cylinder or disc has a number of apertures leading to its periphery, and is free to turn in a fixed circular casing which has a number of projections or stops on its inner periphery to divide it into a number of compartments, The axle is furnished with two distributing apertures, formed near one of the bearings, in which the axle turns, through which apertures the steam enters the interior of the axle intermittently. The bearing is kept pressed against the axle by means of tightening screws, so as to prevent all escape of steam. At each turn of the axle it makes two distributions of steam.—Patent abandoned,

2321 J. Kilner, Wakefield. Glass. Dated July 23, 1868.

makes two distributions of steam.—Patent abandoned, 2321 J. KILNER, Wakefield, Glass. Dated July 23, 1868. The patentee claims the use and application of a reverberatory furnace for the manufacture of glass, by placing the materials requisite to form glass directly on the bed or floor of the furnace without any pots, as usually adopted. The furnace having an arched and inclined roof, the flame and heat, in passing to the main chimney, are deflected upon the surface of the materials, and such materials are quickly fused and kept in a fluid state, as required.—Patent abandoned. Patent abandoned.

quickly fused and kept in a fluid state, as required—Patent abandoned.

2322 J. S. BROOMHEAD and J. WHITMER, Clerkenwell.

Gas regulators. Dated July 23, 1869.

This consists of a cast-from case and cover, with flexible diaphragm, brass ring, and cap. The ring is for the purpose of fixing the diaphragm with screws in its place. A cast-from cover is fitted in its proper position, and screwed on to the flange of the case, the screw passing through the flange of the cover, diaphragm and brass ring, thus affording additional security to and preventing any injury of the diaphragm.—Patent completed.

2323 A. BOCHKOLTZ, Vienna. Pump valces. Dated July 24, 1868.

The object of this is to prevent a waste of motive power, and consists in the employment of self-acting valves actuated by compressed air; the cylinder with the valves is attached to the ordinary cylinder of the engine. It is accomplished by fitting to the interior of a pump cylinder two pistons on one rod, which works through the end covers of the same. The cylinder has two chambers in connection with it; these chambers are furnished with outlets and safety valves. On the up stroke of the piston the air above is compressed, and fresh air is sucked in below, which, on the down stroke, is compressed in a similar manner. This compression of the air at each stroke acts as a cushion, and serves to steady the motion of the main piston at the end of each stroke.—Patent completed.

2324 B. G. HATFIELD, New York. Door rollers. Dated

2324 B. G. HATFIELD, New York. Door rollers. Dated

2324 R. G. HATFIELD, New York. Door rollers. Dated July 24, 1868.

This consists in fitting the axis of a sliding door roller to run in a slot in the casing in which the roller is mounted. The roller casing, which is recessed into the door in the usual manner, is provided on each side with a slot, in which work the ends of the roller axie, the length of the slot being determined by the distance the door has to travel and the relation between the circumference of the wheel and the axies. By this means the axie is caused to roll upon a horizontal plane, thus greatly diminishing the friction, and obviating the necessity of lubricating the working parts. In this manner, a permanently easy motion is ensured with a minimum of friction, the axie and its bearings not being worn away, as heretofore.—Patent completed.

2325 F. H. DANCHELL, Bolton. Utilizing fuel. Dated

or material is placed or driven, which softer metal is not capable of injury by the galvanic action of the bottom plating, or of the sheathing, or only so to a small extent, and is either the bed to receive the fastening or is itself the fastening or the sheathing.—Patent abandoned.

the fastening or the sheathing.—Patent abandoned.
2327 W. R. LAKE, Chancery-lane. Separating cotton
Dated July 24, 1858.

This consists chiefly in making the spike teeth of a
picker machine so that the whole of that portion of each
tooth which is to project radially from the carrying
cylinder shall be thin or flat in its transverse section, and
when the teeth are inserted in the bugs of the cylinder
with their fluttened portions projecting radially therefrom,
the flat surfaces shall be in vertical planes parallel with
each other, and with the planes of the ends of the cylinder.
Thus the thin form of the ends of the teeth will be presented to the rolls of the machine during the continued
wearing away of the teeth, the rolls or the cylinder being
made adjustable in the bearings so as to be readily aftered
in position to compensate for the gradual shortening of in position to compensate for the gradual shortening of the teeth.—Patent completed.

made adjustable in the bearings so as to be readily altered in position to compress for the gradual shoriening of the teeth.—Patent completed.

2328 G. Smith, Camberwell. Forcing fluids. Dated July 24. Isos.

This consists chiefly in the posuliar mode of arranging the blades or plates of rotary engines, so that they may work freely, and yet remain steam-tight during their recolutions around their axis, in the method of hieging or jointing the blades together at the axis, and in the peculiar construction of the outer extremities of the blades, or of pieces attached to the same, to form a steam-tight bearing surface upon the surface of the cylinder. The improvements also consist, partly, in the peculiar construction of the shaft of the eccentric drum and method of attachment of the drum to the shaft, to admit the blades, and to allow the drum to adjust itself laterally on the shaft; also in the employment of loose discs or plates, which are fitted against the ends of the drum and cylinder, between the covers, for the purpose of preventing the escape of steam at those points. The invention also consists in the peculiar arrangement of ports and valves, for the ad dission, exhaustion, and expansion of the steam, and in the means employed to equalize the wearing of the bearing surfaces of the blades, and to diminish friction, where these ports or apertures are formed through the working surface of the cylinder. The invention also consists partly in the peculiarity of arrangement and combinations of the various parts, whereby they are rendered self-adjusting by the pressure of the steam. The rotating blades are hinged together at the centre of the cylinder, upon a pin or rod passing through jaws formed on each blade. The haddes are fitted to slide through packing pieces, extending lengthwise across the drum; these packing pieces are fitted tourn in circular bearings, near the periphery of the drum, and thereby allow the blades to adjust themselves as they rotate, and keep their outer surfaces properly in contact with

nearly in contact with the periphery of the cylinder at one point.—Patent completed.

2329 G. A. Shibirage, Versailles. Practing food. Dated July 24, 1868.

This consists in the preparation of a preserving solution or liquid, and in submitting the animal and vegetable substances to be preserved to the processes hereafter described. The preserving solution is prepared in the following manner:—In 1,000 parts of filtered water, more or less, is carefully mixed 100 parts of non-arcenical sulphuric acid of 66deg. When the solution has been prepared in the manner described, the animal or vegetable organic matter to be preserved is immersed therein. It is allowed to remain on the liquid for about they minutes, at a temperature of about 60 leg. to 80deg, Fah., when it is removed. If the temperature is lower than 60deg, the time of immersion must be lengthened the same proportion as the temperature is lower. The animal or vegetable substance is then submitted to a methodical washing in filtered water, and, if possible, the water is purified with charcoal: the washing is accomplished more rapidly when a current of water is used. Care should be taken in the washing, as in the other operations, to preven tearing the surfaces of the substances which have been submitted to the action of the preserving liquid. The washing is stopped when the surfaces of the animal or vegetable matter are no longer impregnated with the preserving substance.—Patent completed. pregnated with the preserving substance.—Patent com-

door in the usual manner, is provided on each side with a slot, in which work the ends of the roller axle, the length of the slot being determined by the distance the door has to travel and the relation between the circumference of the wheel and the axles. By this means the axle is caused to roll upon a horizontal plane, thus greatly diminishing the friction, and obviating the necessity of lubricating the working parts. In this manner, a permanently easy motion is ensured with a minimum of friction, the axle and its bearings not being worn away, as heretofore.—Patent completed.

2325 F. H. Danchell, Bolton. Utiliting fuel. Dated July 24, 1868.

The object is to supply coal or other fuel in a finely divided state, to close or shut up fireplaces, such as are used for generating steam, puddling, and other purposes. The fuel is blown in by the action of air or steam on to the bars. The invention consists in fitting in front of the furnace a hopper, provided with a rotary feeder, for regulating the supply: the fuel falls into an inclined spout leading to the furnace door. Just in front of the entrance, a steam or air pipe is connected; this pipe is provided with a cock, on opening which a rush of steam forces the fuel out of the spout, and distributes it over the bars, where it is consumed. The steam whichenters is likewise consumed; its action creates a draft and facilitates the consumption of smoke.—Patent completed.

2326 N. Barnaby, Lee, Kent. Sheathing ahips. Dated July 24, 1868.

The improvements consist in forming a cavity in the points of the rivets, which fusion the bottom plates to the frames, and to each other, in which cavity a softer motal in the store of the millstone paraily called with the preserving substance.—Patent completed.

2330 R. Young, Glasgow. Dressing millstones. Dated with the preserving substance.—Patent completed.

2330 R. Young, Glasgow. Dressing millstones per fusion to large the fusion and in arranging the tool to cut in both directions in each growe, whereby the groove is better for

bits are shaped to build together, with a cylindrical form, a little less than the socket, and the bottom corners of their central meeting edges are hollowed to grip the -Patent completed.

their central meeting edges are hollowed to grip the diamond.—Patent completed.

2331 T. WRIGLEY and W. E. YATES, Manchester. Looms. Dated July 24, 1868.

The improvements consist, first, in knitting or forming the healds in the or-linary manner, but constructing them wholly of a fine metal wire material, the upper portion being of a stronger or coarser quality than the lower. Second, in passing the warp threads when leaving the warp beam in their course to the healds over two fixed guide bars, and under a central or movable bar working between them; this central bar is supported in a parallel position with respect to the two fixed guide bars, and is connected at each end to the ends of a rod connected with and actuated by an eccentric on the crank, when in action. This movable vibrating bar regulates the tension of the warp threads during shelding and closing up, diminishing or preventing thereby any great or undue strain upon the warp during the time the shed is being formed. Third, the improvements relate to the temples, and consist in supporting the top temple roller in a swivel or adjustable cap, in which it is supported, and revolves on set screw centres, the box or bottom, or portion of the temple supporting the bottom roller or rollers, being connected by means of a swivel; and, last, the improvements consist in the employment of a flat or suitably shaped adjustable guard placed along and in front of the reed, closely above the open shed. This guard is employed to keep the shuttle in its course through the shed when passing from box to box, thus preventing the shuttle floating or leaving its course.—Patent abandoned.

232 W. E. GEDGE, Strand. Feeding boilers. Dated July 24, 1868.

2332 W. E. GEDGE, Strand. Feeding boilers. Dated July 24, 1863.

This consists in a method of feeding boilers with water. The boiler is surmounted by a reservoir, in communication with the boiler by two tubes; one of the tubes leads into the steam space and terminates in the upper part of the reservoir, the upper end of the other tube is connected to the bottom plate of the reservoir, and is fitted with a valve; the tube leads down into the water in the boiler. When the water sinks bolow a certain level, steam rushes up this tube, lifts the valve, and the water from the reservoir is then free to run down and raise the level.—Patent voir is then free to run down and raise the level .- Patent completed.

2333 B. G. GEORGE, Hatton-garden. Bronzing. Dated

July 24, 1868.

This consists in fitting a hopper above a roller; the bronze, as it falls through the hopper, is taken by the roller and distributed by another roller, below which roller rubs or bears against the paper or fabric as it passes round a drum. The paper being damp where the bronze is to be applied, it adheres thereto; a brush under the drum removes all superfluous powder.—Patent completed.

2334 J. H. JOHNSON, Lincoln's Inn. Iron and steel. Dated

2334 J. H. JOHNSON, Lincoln's Inn. Iron and lited. Dated July 24, 1868.

This relates to a process and furnace for manufacturing cast and wrought fron and steel, whereby the costly blast furnaces employed are entirely dispensed with. The furnace employed is constructed somewhat similar to a reverberatory furnace with a double sloping hearth for the collection of the molten metal. The hearth is heated either by an ordinary fireplace or furnace, or by gas, in which latter case a Siemens or other like apparatus well known to metallurgists would be employed, the flames and products of combustion entering by suitable conduits at one end of the furnace, and passing off by other like conduits situate at the opposite end. Upon each of the sloping sides of the hearth rest the lower ends of a number of vertical fireclay tubes or crucibles without bottoms, such tubes entering at their upper ends into holes in the roof of the furnace, which roof is covered by a cast-iron plate forming a platform, and being provided with movable lids which fit over the mouths of the different openings leading down into the tubes. The ore fluxes and fuel are suitably fed into the several tubes from the platform or plate above referred to, and heat is then applied to the furnace, the flames circulating or playing round the exteriors of the several charged tubes, and effecting the fusion of the ore without coming into setual contact therewith.—Patent completed.

2335 C. Ritchie, Upper Tulse-hill. \*\*Head dress\*\*. Dated

2335 C. RITCHIE, Upper Tulse-hill. Head dress. Dated July 24, 1868.

The patentee proposes to place upon the shoulders a strap, band, or other contrivance, for ensuring fixity to rack socket or arrangement for holding the stem or support which upholds the hat, hood, helmet, umbrella, or other like covering, over the individual.—Patent abandoned.

doned.

2336 J. Young, R. Pollock and J. Morrison, Paisley Prerenting smoke. Dated July 25, 1868.

This consists in causing a large portion of the fire gases which proceed from a furnace to pass again through the fuel along with the air necessary for combustion. In carrying out the invention, the ordinary inlets for air, both below and above the grate bars, are closed, and one or more flues are constructed so as to lead from the ordinary flue to the ashpit, or partly to the ashpit and partly to the space above the grate. A blowing fan or pump, to be worked by any convenient motive power, is arranged in connection with the added passages.—Patent abandoned.

2337 J. STEEL Glasgow. Washing casts. Dated July 25.

2337 J. STEEL, Glasgow. Washing casks. Dated July 25,

2337 J. STEEL, Glasgow. Washing casts. Dated July 25, 1868.

The apparatus comprises a large disc or chuck plate fixed on the overhanging end of a horizontal shaft, made to revolve backwards and forwards at any convenient speed. A series of cradles to receive the casks are arranged with their axes tangent to a circle on the face of the disc, and are mounted on journals connected by bevel gearing with each other, and actuated by gearing. The casks are placed in the cradles with their axes coinciding with the cradle journals, and when the machine is in action each has a rotation about its own axis, combined with the motion due to being carried round by the rotating disc. There may be two large discs one on each end of the shaft, and they may be provided with cradles for different sizes of casks. The gearing for imparting the axial rotation to the cradles consists of a bevel toothed ring encircling the main shaft, but fixed to the framing, and having in gear with it a bevel wheel on a radially disposed shaft carried upen the disc. This radial shaft rotates in consequence of being carried round by the disc, and it imparts motion by bevel gearing to one of the uradle journals.—Patent abandoned.

2338 J. GREENHALGH, Oldham. Cleaning cotton. Dated July 25, 1868.
The first improvement consists in a new mode of supplying the cotton or other material to the machine by means of a creeper and pair of fluted rollers, which are combined with a third roller placed in front of the pair and over the creeper. The creeper and rollers have not, however, a continuous motion given to them, as in other machines, but have an intermittent motion, that is, they stand still a certain time, then move on a certain quantity, and again stand still, and so on. This intermittent motion is effected by means of a toothed sector fixed on a large spur wheel, at every revolution of which it acts upon a pinion, from which motion is communicated to the creeper and feed rollers. It also consists in the application of a flap door or slide placed at the top of the machine, which is opened at proper intervals by means of antifriction bowls, turning on studs on a large spur wheel. These bowls, by acting on a lever, open or close the flap door or slide is closed whilst the operation of feeding is going on. The flap door is enclosed in a cowl into which the cleuned material is discharged on the flap door being opened. From the cowl, the cleuned material is carried away to a receptacle prepared for it either by a current of air or by another creeper, as may be convenient. The third improvement consists in varying the mode of feeding the material to the machine. A flake is used of the usual construction, but which is opened and closed by the action of the large spur wheel. The flake is held closed in its working position by a latch.—Patent completed.

2339 C. E. Brooman, Fleet-street, City. Drying tissues. (A communication.) Dated July 25, 1869.

working position by a latch.—Patent completed.

2339 C. E. BROOMAN, Fleet-street, City. Drying tissues.
(A communication.) Dated July 25, 1863.

This relates to apparatus in which the drying is effected by means of air. Within a chamber an apron or diaphragm of metallic cloth is fitted, on which the wool or other illamentous material to be dried is placed. This apron is supported by walls, which prevent the entrance of the air through anything else than through meshes or openings in the apron. Under the whole length of the apron is a compartment conflued by the walls, at one end of which a large pipe, to act as an escape pipe, is fitted, which pipe may be carried up through the roof of the building, or otherwise, and into which all the air drawn through the apron is made to pass. A double action air ferce pump is placed within another chamber in close proximity, wherein is also placed a reservoir in which the compressed air from the pump is collected. From this reservoir the compressed air passes through a pipe into the interior of the large pipe at the bend thereof, and, issuing up, the larger pipe sucks or draws the air from the compartment under the apron away to the outer atmosphere.—Patent abandoned.

2340 C. D. ABEL, Chancery-lane. Separating metals.

atmosphere.—Patent abandoned.

2340 C. D. Abell, Chancery-lane. Separating metals.
Dated July 25, 1868.

This consists, when the argentiferous alloy has been obtained (by "Parks" process in the separation of silver from lead by zinc), in submitting the alloy to successive liquidation processes, so to remove therefrom the greater portion of the lead combined therewith. This product, broken up into small fragments and mixed with its own weight of litharge, is thrown on to the bed of a reverberatory furnace. The bed of this furnace rests upon two cast-iron plates, made to incline towards each other in the centre. The alloy having been charged into the furnace, it is covered with a small quantity of litharge and it is heated to a dark red heat. The reactions then commence, one portion of the litharge is soon reduced by the zinc which is transformed into oxide, which remains floating in the molten mass, while the lead produced absorbs all the silver, and is caused to runoff through an outlet passage into a receptacle placed outside the furnace to receive it.—Patent completed.

2341 J. Brigham and R. Bickerton, Berwick-on-Tweed.

an outlet passage into a receptacle placed outside the fernace to receive it.—Patent completed.

2341 J. Brigham and R. Bickerton, Berwick-on-Tweed.

Drill rollers. Dated July 25, 1868.

This consists essentially in the construction of drill rollers composed or formed of a series of narrow discs or ring wheels. These narrow wheels being mounted on a hollow spindle, either plain, parallel along the outside, or made stepped, and eccentrically, in the reverse directions on the parts, where the eyes of the alternate wheels work, or have the cyes made large, and with flats or undulations on the bearings or on the shaft. It also consists in the construction and arrangement of the parts and mechanism for the regular delivery or deposit of seeds; also, in attaching a small seed delivery cylinder, open at one end and close at the other, to the usual horizontal revolving spindle for actuating the seed delivery mechanism, actuated by a toothed wheel from a corresponding wheel or pulley. Within the open end of the cylinder, an annular tapered ring plug is made to slide by two guiding and actuating rods, out through which the delivery cylinder revolves which rods may be actuated or regulated by a screw boss on the spindle, or a cross head and screw pin or lever on the side of the seed box, so as to push the plug into or out of the open ned of the cylinder, and so regulate the size of the openings at the bottom of the segmental checks, where they pass into the spiral channels leading to the holes out through the cylinder, to any desired size of seed, to deliver one (or more if desired), every time a wedge groove comes round.—Patent completed.

2342 A. V. Newton, Chancery-lane. Portable railway.

pleted.

2342 A. V. NEWTON, Chancery-lane. Portable railway.
Dated July 25, 1868.

This invention is based upon the self-rail laying principle, and consists chiefly in arranging on eithor side of a carriage a continuous or endless rail, or set of rails, with a corresponding arrangement of trucks adapted thereto, the trucks being connected into endless chains fitting around the rails. Each truck carries a set of rollers running on the rail, and turning in journals on the truck; they are kept in constant contact with the outside of the rail by means of an additional wheel working on the inside of the same. As the vehicle is drawn forward, or as the trucks ar moved on the rails by muscular or other power, each truck, as it comes to the ground, rests upon a foot formed upon it, while the rail is being carried forward over it, and is then carried up again in rear of the vehicle. On water craft, buoys instead of feet are provided, the same acting as paddles to convey the vessel forward.—Patent completed.

2343 L. Wray, Ramsgate. Separating metals. Dated

2343 L. WRAY, Ramsgate. Separating metals. Dated July 25, 1868.

The first object is to crush up the ore, and the second to triturate the ore or substance containing the metal until it is reduced to an almost impalpable powder. The

first machine consists of three or more grooved rollers, two of which are arranged to gear into each other, and the third is placed above and rosts on the lower ones, and by its weight crushes the ore, which in a divided state passes down to the other two, where it is ground or crushed up small, after which it passes through a bulling machine to the triturating machine. This triturating machine consists of a barrel or hollow eylinder provided externally with projecting grooves, hoops, flanges, rings, or other analogous dovices, which will admit of the cylinder or barrel being placed on and rolled along a railway, for the purpose hereafter explained. An opening is made in one end of the cylinder for the purpose of obtaining access to the interior; also, an opening for charging or discharging the machine. Inside this cylinder is placed a spherical roller, which may be either plain, serrated, or grooved on the surface, for more effectually acting upon and grinding up the substance. The amalgamating machine consists of a seemicircular trough, which is heated by means of a steam jacket below, and in this vessel is placed a shaft or axle, on which are mounted any number of metal discs, the surfaces of which may be plain or corrugated, and are to be amalgamated or prepared with mercury or amalgam, in the well-known manner, when treating auriferous and argentiferous ores. A quantity of mercury is also placed at the bottom of the trough, and the disc shaft is mounted in suitable bearings, which, if desired, may be removable or capable of being lifted out with the shaft. Rotary motion is communicated to the shaft and the discs thereon by causing a driving roller to rest on the top edge of the discs, and actuating this roller by any suitable gearing.—Patent completed.

2344 R. Newton, Leeds. Straightening fibres. Dated July 25, 1868.

completed.

2344 R. NEWTON, Leeds. Straightening fibres. Dated July 25, 1868.

This invention relates to the opening and straightening or fibres, by the use of endless sheets, furnished with steel pins or combs, and so arranged as to clear each other at the same time that they straighten the fibres passed through the machine. The fibre is hwhich the machine is chiefly designed to operate are flax, and hemp, tow, jute, and waste silk. The fibre is fed into the machine, between two encless sheets furnished with steel pins. From these sheets it is delivered to or stripped off, by a rapidly moving endless sheet of combs, fitted with stripper batts, which, when brought into action, push the fibre from the combs, on to an endless sheet of hackles. This sheet of hackles carries forward the fibre to a pair of delivery rollers, which deliver it in an opened and straightened state out of the machine.—Patent completed.

2346 W. R. Lake, Chancery-lane. Boilers and feeding.

hackles carries forward the fibre to a pair of delivery rollers, which deliver it in an opened and straightened state out of the machine.—Patent completed.

2346 W. R. Lake, Chancery-lane. Boilers and feeding. (A communication). Dated July 25, 1838.

The exterior shells of the boilers consist of a series of plates of boiler iron bent and riveted together, so as to produce a long flattened boiler with convex ends, tied together by the perforated vertical longitudinal partition plates. Each of the chambers is divided by the vertical tranverse partition plates into separate compartments, the partition plates being only but half the height of the boilers in which they are fixed. The boilers are arranged, so that one will be directly above the other, a return flue being left between them. The overflow pipes are each secured in a vertical position, and extend through the shells of the boilers, the lower end of each pipe opening fully into the lower boiler without projecting downwards into the same, and the upper end of each pipe projecting into the supper boiler, and opening into the same at the intended water line or at about half the height of the boiler. The two boilers are intended to be "walled in," in any suitable manner, so as to afford a fire space or furnace under the front end of the lower boiler, with a direct flue extending back therefrom, and up behind the rear on i of the boiler, into the return flue, left between the two boilers, the latter flue being continued upwards in front and back, over the top of the upper boiler, to an escape flue or chimney. The float is a large hollow airtight sphere of thin metal, with a rigid stem fitted to slidensily through a stuffing box, fitted on the upper boiler. The lower side of the case communicates with the boiler, through an opening, and its upper side communicates with a opening through one of its sides, and is fixed concentrically upon a shaft, so that it can be rotated thereby, in a case which is lixed upon the top of the upper boiler. The lower side of the ca

336 J. R. Johnson, Haymarket, Middlesex. Improvements in the manufacture or production of photographic ments in the manufacture or production of photographic ments in the manuscentre of process.

337 L. Wray, Ramsgate, Kent. An improved process for carbonizing and hardening wrought iron.

338 A. V. Newton, Chancery-lane. Improvements in sewing machinery. (A communication).

339 J. Howard, Bedford. Improvements in the construction of turn-wrest ploughs.

239 J. Howard, Bedford. Improvements in the construction of turn-wrest ploughs.

Dated February 4, 1869.

340 H. and J. Bryceson and T. H. Morten, Stanhopestreet, Euston-road, St. Panoras, Middlesex. Improvements in the construction of organs, and in the application of electricity and hydraulies thereto.

341 T. Parkinson, Liverpool. Improvements in, and connected with doors for regulating the admission of air to furnaces.

connected with, doors for regulating the sumission of air to furnaces.

342 J. J. Bagshawe, Thames Steel Works, Sheffield, and W. F. Betho, Birmingham. Improvements in machinery for manufacturing semolina and flour, and in apparatus for producing portions of such machinery.

343 E. D'Artois, Charlotte-street, Filzroy-square, Middle-sex. An inkstand which is called d'Artois's inkstand.

344 T. and T. Pankhurst, Clover-street, Chatham, Kent. Improvements in gully traps.

345 E. Lord, Tormorden, Yorkshire. Improvements in furnaces for steam boilers and other purposes.

346 P. Jensen, Chiswell-street, Finsbury-square, City. Mode of utilizing the motion of the waves relatively to that produced by them on the ship, for the propelling of the same, or for other useful purposes. (A communication).

same, or for other useful purposes. (A communication).

347 R. W. Mnowles and G. Green, Tong, near Bolton, Lancashire. Improvements in machinery or apparatus for stretching, swissing, and finishing muslins or other similar fabrics.

348 J. Vavesseur, Gravel-lane, Southwark-street, Surrey. Improvements in apparatus for working heavy guns or ordnance.

Improvements in apparatus for working neavy guns or ordnance.

349 E. Morewood, Rock Cottage, Briton Ferry, Glamorganshire. Improvements in the manufacture of tin and terne plates.

350 G. Bray, Deptford, Kent. An improved slip hook.

351 W. E. Newton, Chancery-lane. Improvements in elevated and other railways. (A communication).

352 H. Jones, Duchess-street, Portland-place, St. Marylebone, Middlesex. Apparatus for sounding tuning forks.

Dated February 5, 1869.

353 G. and E. Ashworth, Manchester. Improvements in the method of manufacturing paper fasteners, and in the apparatus employed in the manufacture thereof.

354 J. Joheon, Derby. Improvements in explosive projectiles.

364 J. Jobson, Derby. Improvements in explosive projectiles.
355 F. Braby, Camberwell, Surrey. Improvements in the treatment and utilization of the waste solution of sulphate of from resulting from the cleansing of fron surfaces in the process of galvanizing.
356 W. Blundell, Upper Thames-street, City. Improvements in guards or apparatus applicable to chimneys for the prevention of down draught.
357 J. Page, Glasgow. Improvements in pipe joints, and in cement for the same, and applicable otherwise, and in cement for the same, and applicable otherwise, and in cement for the same, and applicable otherwise, as J. Henderson, Leith, Mid Lothian. Improvements in surface condensers and refrigerators.
359 W. Adams, Carlisle-terrace, Bow, Middlesex, and W. G. Beattie, Surbton, Surrey. Improvements in the bearing springs of carriages, trucks, and engines used on railways and common roads.
360 J. Taylor. Britannia Works. Eirkenhead. Chester.

Improvements in machinery or apparatus for raising, lowering, and conveying bodies.

361 J. H. Johnson, Lincoln's Inn-fields. Improvements

Improvements in machinery or apparatus for raising, lowering, and conveying bodies.

361 J. H. Johnson, Lincoln's Inn-fields. Improvements in mounting and working ordnance. (A communication).

362 J. Halford, Brettel-lane, Kingswinford, Staffordshire. Improvements in puddling furnaces used in the manufacture of iron, and in other reverberatory furnaces, as A. Clark, Chancery-lane. Improvements in mules for spinning yarns. (A communication).

364 A. Browne, King William-street, City. A process for the direct decomposition of neutral fatty substances for the manufacture of stearlne. (A communication).

365 D. D. Kyle, Victoria-street, Westminister. Improvements in the means of, and apparatus for, communicating or signalling in and with railway trains.

366 C. G. Hill, Nottingham. Improvements in the manufacture of rosettes and trimmings.

367 C. S. Dawson, Thames Ditton, Surrey. An elastic stamp for printing on paper, linen, parchment, wood, stone, glass, metal, or any other suitable material.

368 H. A. Dufrene, Rue de la Fidelite, Paris. Improvements in the manufacture of ice, and of the agents employed therein, and in the apparatus connected therewith (A communication).

369 J. S. Offord, Norwich, Norfolk. Improvements in apparatus for clipping and shearing the coats of horses and other animals.

370 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in puddling and other furnaces employed in the manufacture of wrought iron and steel. (A communication).

371 R. Snook, New-street, Horselydown. Improvements in cocks, taps, and valves for regulating the supply of steam or water or other fluids.

372 J. C. Shaw, Patricroft, near Manchester. Improvements in machinery or apparatus for cutting wire and rods of metal and other materials. (A communication).

373 J. T. Edmonds, City-road, Middlesex. Improvements in machinery or apparatus for giving medicines and drinks to horses and other cattle.

374 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved compound for preparing jolly broth, (A com

esparto grass, straw, and other fibrous substances in the working and incinerating of the residue resulting from

working an evaporation.

376 E. Meldrum, Dechmont, Linlithgowshire, Improve

evaporation.

376 E. Meldrum, Dechmont, Linlithgowshire. Improvements in the manufacture of parafiln oil.

377 T. Harrison, Burton-road, Lincoln. Improvements in corn, seed, and manure drills.

378 B. Walker and W. Tilson, Lenton, Nottinghamshire. Improvements in jacquards, and in reading machines connected therewith, and in the means or apparatus employed therein.

Dated February 8, 1569.

379 E. W. Hawes, Balmoral Lodge, Clintarf, Dublin. Constructing buoys and other floating sea marks according to the drawings and provisional specifications herewith annexed.

380 T. Nichols and J. Parr, Talke, near Lawton, Chester. Improvements in signal bells.

381 L. Strauss and A. Seckbach, Watling-street, City. Improvements in the method of, and apparatus for, preserving, improving, and discharging beer and other beverages. (A communication).

332 E. J. D. Fossard, Paris, Rue Albouy. An improved clyster-pump.

332 E. J. D. Fossard, Paris, Rue Albouy. An improved clyster-punp.
383 R. W. Row, Alton, Hants. Improvements in solitaires, links, and fasteners, applicable to gloves, belts, bands, and other like articles.
384 J. H. Johnson, Lincoln's Inn-fields. Improvements in steam engine governors. (A communication).
385 O. Sarony, South Cliffs, Scarborough, Yorkshire. Improvements in photographs to give them artistic effect, and to produce enlarged and permanent pictures from small negatives.
386 W. R. Lake, Southampton-buildings, Chancery-

to produce characteristics.

I negatives.

W. R. Lake, Southampton-buildings, Chancery-An improved lining for puddling and other furs.

A communication.

W. R. Lake, Southampton-buildings, Chancery-Improvements in knitting machines. (A commu-

lane. Improvements in knitting machines. (A communication).

388 B. Hunt, Serle-street, Lincoln's Inn. An improved manometric-barometric apparatus and vacuum gauge, applicable also as a safety valve. (A communication).

389 H. J. Richman, Porchester-terrace, Middleex. Improvements in fans or apparatus for forcing or drawing air. (A communication).

390 F. Jenkin, Fittis-row, Edinburgh. Improvements in apparatus for producing electric light.

#### **MECHANICS'** MAGAZINE.

LONDON: FRIDAY, FEBRUARY 19, 1869.

DR. TYNDALL'S RESEARCHES LIGHT.

IN a recent Royal Institution lecture, as already published in these columns, Professor Tyndall exhibited some experiments tending towards the explanation of the long-standing puzzle of the blue colour of the sky. A few detailed particulars as to the condi-tions necessary to obtain the blue cloud seen in his experiments may not therefore be un-interesting. He has several tubes in which the clouds are produced, the one commonly used being a yard long and two and a-half inches in diameter. As we have already explained, the common air used in the experiments is purified from dirt by filtration through cotton wool, after which the carbonic acid is removed by the passage of the air through pumice stone soaked in caustic potash, and, lastly, it is dried by means of some sulphuric acid and nowdered class consome sulphuric acid and powdered glass consome surprire acid and powdered glass con-tained in a second U-tube. The purified air is then charged with any desired vapour by permitting it to bubble through a liquid from which it takes up the vapour. The liquid is contained in the bottom of a little Woulfe's bottle made of a test tube, with one length of glass tube passing through the cork and below the surface of the liquid, while the second and shorter piece of tube merely pierces the cork, and has its outer end connected by means of a stopcock with the experimental glass cylinder. This great tube is first exhausted of air, and then, when the stopcock con-nected with the Woulfe's bottle is turned on, the air rushes from the room through the cotton wool, the purifying agents, and the liquid in the Woulfe's bottle, and enters the great hollow glass cylinder more or less charged with vapour. The great tube has transparent ends of glass, so that the beam from the electric lamp may be sent along the axis of the tube, and the action of the light upon the vapour be observed. The beam may be made to assume a conical form, or may pass in parallel rays, according to the position of the condensers of the electric lamp.

Some of the vapours tried in the experiments resisted the action of light, but a second vapour, tending to produce a decomposing action upon the first one, was sometimes also admitted, and the admission of the light into the tube then produced sufficient molecular motion to begin the decomposition. In one of the earlier experiments, the tube was charged with half an atmosphere of air and nitrite of butyl vapour, and half an atmosphere of air which had been permitted to bubble through commercial hydrochloric acid. When the beam of light was sent through these vapours, the action paused just long enough to show that the tube was optically empty; then a cloud was formed which began blue, but advanced to whiteness so rapidly as to justify the assertion that the whole action was practically intion that the whole action was practically instantaneous. It remained, therefore, to try to lengthen the time of this action, and to bring the blue colour more under observation. In another experiment, as reported by Dr. Tyndall to the Royal Society, "the mixed air and nitrite of butyl vapour was permitted to enter it, until the associated mercury column was depressed 1-10th of an inch. In other words, the air and vapour, united, exercised a pressure not exceeding 1-300th of an atmosphere. Air, passed through a solu-tion of hydrochloric acid, was then added, till generally turned when a new feature in the mercury column was depressed 3in. The

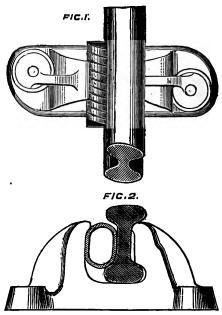

condensed beam of the electric light passed for some time in darkness through this mix-ture. There was absolutely nothing within the tube competent to scatter the light. Soon, however, a superbly blue cloud was formed along the track of the beam, and it continued blue sufficiently long to permit of its thorough examination. The light discharged from the examination. The light discharged from the cloud at right angles to its own length was perfectly polarized. By degrees, the cloud became of whitish blue, and for a time the selenite colours obtained by looking at it normally were exceedingly brilliant. The direction of maximum polarization was discretized at wight angles to the illuminating tinctly at right angles to the illuminating beam. This continued to be the case as long as the cloud maintained a decided blue colour, as the cloud maintained a decided blue colour, and even for some time after the pure blue had changed to bluish white. But as the light continued to act, the cloud became coarser and whiter, particularly at its centre, where it at length ceased to discharge polarized light in the direction of the perpendicular, while it continued to do so at both its ends."

The vapours were also tried in a more attenuated condition, and were found to produce a blue equally rich, but more durable. The blue colour is not visible in daylight, but only when the cloud is itself the chief source of luminosity. The cloud acts like a Nicol's prism, for when a real Nicol's prism is placed between the experimental tube and the lamp, if the cloud looks of a rich blue, when viewed from above or below, the effect wholly disappears when viewed in a horizontal direction. Supposing the water par-ticles in the atmosphere of the earth to take the form of incipient cloud, as is the case with the vapours used in these experiments, the fact is sufficient to account for the blue colour of the sky. It is true, that the polariz-ing angle of the light of the sky is not the same as that of water, but, says Dr. Tyndall, "whenever the precipitated particles are sufficiently fine, no matter what the substance forming the particles may be, the direction of maximum polarization is at right angles to the illuminating beam, the polarizing angle for matter in this condition being invariably 45deg." Motes in liquids will polarize light. Professor Tyndall states that a cell of distilled water in front of the electric lamp will polarize the light very slightly, but when a piece of soap is agitated in the water above the beam, the light becomes so polarized that selenite can be made to flash out the usual vivid colours under the action of the ray; a drop of "hair-wash," or of mastic dissolved in a large excess of alcohol, will produce the same

# COILED IRON RAILWAY KEYS.

MANY attempts have been made to supersede the wood keys, by means of which rails are held in place in their chairs, by keys both of wrought and of cast iron. Some systems have failed on account of their complex and expensive character; some from the inherent and ineradicable defects they were found to possess; whilst others, of a more practical nature, have not got beyond the ordeal of experimental trial. This has been owing, in England, either to want of patience or cash—more frequently the latter on the part of inventors, or from an objection, on the part of railway managers, to depart from the ordinary method of keying the rail in the chair. In India, however, where the influences of the climate and the ravages of the insect tribe render wood the least desirable material for permanentrallway purposes, iron is readily adopted, its primary expense, heavy though it is, being a far smaller and less serious matter than that of the constant renewal of timber, and the

could fill several columns of our paper in merely describing the various methods which have been proposed for fastening rails in chairs with iron keys, were we disposed to do But such is not our present purpose, our object being to bring before our readers an excellent form of railway key which has just been introduced to public notice by Messrs. Thomson and Browning, of 3, Victoria-street, Westminster. This is the patent coiled iron key, which is shown, as applied to an ordinary railway chair, in the accompanying cuts, in plan at fig. 1, and in elevation at fig. 2. These

keys are the invention of Messrs. Muir and M'Ilwham, of the Anderston Foundry, Glasgow, and they are made by coiling a flat gow, and they are made by coming a nate strip of iron upon a steel mandril of the required form. They are coiled cold, so as to preserve the elasticity of the iron, and are finished by being warmed and dipped in boiled linseed oil, which forms a strong weatherproof varnish upon them. They are easily driven, either in or out, with a rammer made for the purpose, but they cannot work loose in the chairs. They grip the rail firmly, but without rigidity, and require no tightening up or attention, when once fixed in place, and they are as durable as the chair itself. We understand that, after a sufficient trial, it has been decided to introduce the use of these keys generally on the Great Indian Peninsular Railway. We may add that the keys for a 75lb rail weigh a little over 2lb each. Railway engineers would find these keys advantageous in this country, where wood keys are generally short lived, and require constant attention. In India, however, and in some of the colonies, where wood keys are practically useless, the coiled iron key will prove an undoubted boon, and, we should think, will meet with general adoption.

# STORM SIGNALS.

RESPECTING the subject of storm signals, our contemporary, "Scientific Opinion," appears to be a year or two behindhand in its information. The number for the 10th inst. has an article headed "Weather Science," which, after stating that meteorology "has, up to this, failed to give us any satisfactory means of predicting the weather," rather unreasonably goes on to deprecate the dis-continuance of the late Admiral Fitzroy's storm warnings, and to urge their resumption. Now, the fact is, the Meteorological Committee have been issuing the storm warnings, in a modified form, regularly since the commence-ment of 1868. It is true, that they employ risk of accident from defective joints and sleeperage. To India, therefore, attention is generally turned when a new feature in iron permanent way makes its appearance. We the MECHANICS' MAGAZINE has repeatedly

advocated; nevertheless, from all that we can ascertain, the signals, combined with "tele-graphic weather intelligence," also issued by the Meteorological Office, are greatly appreciated by the shipping and seafaring community. More than 100 stations on our coasts nity. More than 100 stations on our coasts hoist the drum upon information received from the Meteorological Office of impending gales or their actual advent upon some portion of our shores, and a like signal is duly made at all our home naval ports. Several foreign ports, Hamburg among them, receive warnings from this country, and exhibit a similar signal. The Meteorological Committee have also under trial, "wind semaphores" at Liverpool, Shields, and in the Thames at Blackwall. By means of this apparatus, it is proposed to indicate the direction of wind and its force, whenever dangerous and threatening, as well as the district from which it was reported to the central office; so that shipowners, shipmasters, and underwriters may form their own opinion as to the probable extension of the gale, and the advisability of ships leaving port under the circumstances. All this should have been known to a writer professing to give a scientific opinion; and, if known, its pretensions should have been duly considered, although the system may not go the length advocated by him and desired by ourselves.

# MANUFACTURE OF CAPS AND CARTRIDGES.

No. III.

IN our last article we described the manufacture of the facture of the caps constituting a portion of the entire cartridge. Cotemporaneously with their fabrication is carried on that of the small copper sockets forming the base of They are cut out of yellow the cartridge. copper, which arrives at the establishment in the form of narrow strips, having a breadth of two and a-half inches. This width is sufficient to permit of three sockets being cut out of it, and the operation is performed by means similar to those employed for the manufacture of the caps. They consist of a die and punch, the latter being furnished with a small circular knife, which cuts the edges of the copper so soon us the stamping is effected. At the close of a full day's work, these machines can show that they have turned out each 150,000 of these sockets. These emerge from the punch in a greasy state, similar to the caps; but, unlike the former, the operation of cleaning them is not immediately carried into effect. It depends upon what description of cartridge they are intended for. Some are are their greasy condition to the factory at Rue Amelot, or to that at Moulineaux, while others are despatched to the establish-ment at Rue Nôtre-Dame des Victories. If they are intended to be used in small arms upon the Flobert principle, whether pistols or cavalry carbines, they have to undergo an enlargement in the direction of their length, so as to be able to contain the whole of the cartridge, instead of merely constituting the base of it. In this case, they are annealed, cleaned, and lengthened by being passed through a mill, which carries a couple of punches, and punches them out to the required size. They are subsequently polished by friction, in a manner similar to that employed for the caps. The sockets destined for central-fire cartridges differ from the other descriptions, by being furnished with a brass cup or chamber in which the priming is placed, and which also carries a small knob answering to the nipple in percussion fire-arms. This little cup is cut out of strips of brass in a very ingenious and rapid manner, by the aid of a machine consisting of a punch and die. The sheath, so to call it, is cut out, stamped, and cleft, the edges of the cleft portions being slightly turned up, and giving it the appearance of the calyx of a flower, with the extremities of the petals raised a in bundles of four at a time, are brought under to a minion to barrel C, secured to the lever D at the bottom of the lock E, which is placed in the centre of the stock F. The striker G is within the breech-piece A, and works easily with the extremities of the petals raised a in bundles of four at a time, are brought under

little upwards. Motion is communicated to the stamping machinery by rods and eccentrics, and 170,000 cups is the daily work of each machine. These chambers or cups carry the needle or percussive agent, which are of brass wire, cut into lengths, and placed in a triangularly shaped hopper, from which they drop, one by one, in order to undergo sharp-ening, by the action of a small lathe, strongly resembling those used in manufacturing the axles of wheels in clockwork. The knobs or nipples are also made from brass wire, the cross section of which gives a star with four branches or arms at right angles to one another. These, together with the envelopes, may be regarded as the principal component parts of the cartridges, and the manner of putting them together will be fully described as we proceed with the subject.

Felt and pasteboard are the chief components of which the envelope, or cartridge proper is constructed. The wads are made of the former material, and constitute a separate branch of industry, no fewer than eighty persons being employed upon them alone. In the first place, the felt has to be specially manufactured, and the hair of calf skin, in the incipient stage of tanning, is selected as the proper material. This hair, or the coats, as they may be called, are subjected to a preliminary beating, and then placed in a ma-chine to be teased. This machine is composed of a series of cylinders, which separate the hairs. They are then acted upon by a cylinder furnished with brushes, and being drawn up by a powerful blast from a ventilating machine, arrange themselves between the grooves of a couple of other cylinders. Subsequently, they are drawn out in the form of a sheet, and spread upon an endless band having a very slow motion. At the same time, three cylinders revolving with a reciprocating motion exert a certain degree of friction upon the hair, which commences the felting and produces a "galette." These "galettes," which are of the same consistency as what hatters term "hat body," are passed on to the workmen who finish the felting. For the workmen who main the fetting. For this purpose, they are dipped in water con-taining about one per cent. of sulphuric acid, and beaten and compressed with a roller of wood, until they assume the character of a piece of solid stuff. The finishing felting process is also accomplished by machinery. Instead of being beaten and polished by hand labour, the "galettes," after being steeped in the acidulated water, are wound round iron shafts, revolving slowly on the top of an iron table which moves with a come-and-go motion. The hair compressed between the shaft and the table speedily becomes incorporated, and endowed with a firm homogeneous texture. Directly this operation is completed, the pieces of felt are made up in bundles, and subjected to a strong pressure in a hydraulic press, which forces out any moisture they may contain. After being dried, they are steeped in a mixture of rye flour and glove powder, in which there is a small quantity of the parings of the skins of which gloves are made, and which serves to give a consistency to the mixture, which it would not otherwise possess. Again the pieces of felt are put under the hydraulic press, and again consigned to the drying room, and, when completely dry, a strong coating of the paste is spread over them, upon which paper is laid. A third visit to the drying room, where it is necessary to raise the temperature very high, in order to cause the paper to adhere very closely, completes the operation. In their finished state, the pieces of felt are taken to the cutting machine, where the wads are cut, or, rather, punched out, in a manner very similar to that employed in the case of the metal plates already described. Each of these machines can turn out a quarter of a million

the action of the punch by a bar having two motions. The one is a lateral motion, taking place at the fall of each wad, and the other, a movement from back to front, occurring so soon as each sheet is removed. These motions are calculated with such precision that there is very little slip. In the other machines, the feeding is done by hand. The shape of the wads is tested by the hand, but the thickness is ascertained by the aid of a small and ingenious machine. In the case of rifles, and what are termed arme de precision, the length of the cartridge must be regulated to a nicety. A discrepancy amounting to 0.04 of an inch would be sufficient to seriously interfere with the accuracy of the weapon. There must always exist a trifling difference in the thickness of the envelopes, since it is absolutely impossible to cover felt with paper, in a manner that will insure perfect uniformity in this respect. The separation or sorting of cartridges that have different thicknesses is effected by placing upon an endless band a certain number of wads, the shape of which has been previously ascertained to be correct. At a given distance along the band, a grooved cylinder is placed, which allows the wads only to pass that have a thickness less than 0.36 of an inch. These are arrested by a second cylinder, furnished with sharp points, which takes them up, carries them round as the shaft rotates, and brings them into contact with a copper comb. They are brushed off the points by this comb, fall into an inclined trough, and are ultimately deposited in a box placed for the purpose. The first batch is thus accounted for, and it remains to be seen how those having a still less thickness are disposed of. Manifestly, the next in order, or those having a thickness of 0.28in., will not be taken up by the points of the first cylinder, but will be carried on by the motion of the endless band. So soon as they have left the first cylinder a little behind, they are, in their turn, caught by the point of a second cylinder, treated in the same manner as those they were just separated from, and deposited in a separate receptacle. A third batch having a thickness less than a quarter of an inch, is seized upon in a similar manner, by a third cylinder, and finally conducted into a box placed at one end of the apparatus. The whole of these operations are conducted with great rapidity, smoothness, and precision.

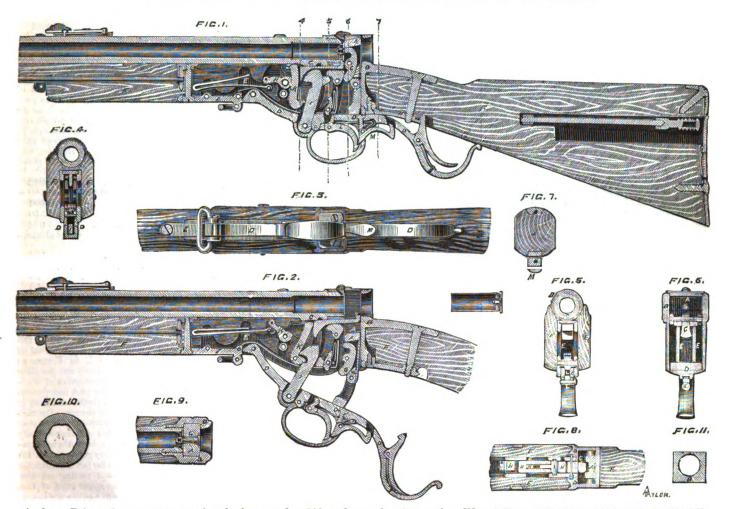

# THE SOPER BREECH-LOADING RIFLE.

N pursuance of an intention expressed some time since to give our readers particulars of such breech-loading rifles as proved themselves, by their performances or other merits, worthy of notice, we illustrate herewith another rifle of this class. It is the invention of Mr. W. Soper, of Friar-street, Reading, and its mechanism is clearly seen from our engraving. Fig. 1 is a longitudinal section of the rifle, with the parts shown in their position after the firing of a shot. Fig. 2 is a similar section, showing the position of is a similar section, showing the position of the parts at the moment of ejecting the empty cartridge case. Fig. 3 is an underside view of the lever, &c. Figs. 4, 5, 6, and 7 are vertical cross sections, looking towards the muzzle. Fig. 8 is a horizontal section show-ing the lock and breech. Fig. 9 is a hori-zontal section through the breech wedge and barrel. Fig. 10 is an enlarged vertical section of the barrel, showing the rifling; and fig. 11 is the back surface of the breech upon which the wedge bears during the explosion of the cartridge.

The breech-piece A is formed of a piece of

steel which works up and down in a vertical slot made in the breech-shoe B at the rear of the barrel C, secured to the lever D at the

# THE SOPER BREECH-LOADING RIFLE.

the lever D in such a manner as that both second at 500, and second at 800 yards. cock and breech-piece work simultaneously by means of the swivel I, which passes through the centre of the cock H. The swivel I is provided with a projection and a recess suitable for working the ejecting lever K, so that by one motion the breech is lowered, the lock is placed at full cock, and the old cartridge case is ejected sharply in rear of the firer. This portion of the mechanism is so simple and so effective that, during the trials at Woolwich, the Wimbledon competitions for 1867 and 1868, and several other public trials, in which many thousands of rounds have been fired, we are informed that not a single hitch or failure has occurred. The trigger L is mounted on the lever D, and has therefore no connection with the lock until the breech is placed in its right position for firing. reinforce or safety trigger M is also mounted on the lever D, which acts upon the trigger L in such a manner as entirely to prevent its being released until the safety trigger M is first pressed. This operation is performed by the firer gripping the rifle in the Hythelposi-

It will thus be seen that the ordinary half-cock is entirely dispensed with, the rifle, when loaded, being always in a perfectly safe condition, and, at the same time, always ready for instant action, the firer having only to press the trigger L when he has taken his aim. The performance of this wife at West. aim. The performance of this rifle at Woolwich was pronounced by the Select Committee to be, for accuracy, "good," and for rapidity it excelled every other submitted; but was rejected by them on the ground that the breech mechanism was too complicated, and, in their opinion, the safety catch was not a satisfactory substitute for the half-cock. In the competition for the Duke of Cambridge's prize at Wimbledon, last year, this rifle stood first in order of merit at 200, worthy of notice.

are informed that the highest score at 200, and the third at 800 yards, were both made by gentlemen who had never seen the rifle before going to Wimbledon. At the 200 yards' range, out of the 24 highest scores made during the meeting, Mr. Soper informs us that 10 were made with the Soper rifle, us that 10 were made with the Soper rifle, although it was only tried 16 times; 6 were made by the Henry in 50 trials; 2 by the Kerr in 29 trials; 1 by the Snider in 10 trials; 1 by the Westley Richards in 6 trials; 1 by the Cooper in 4 trials; and 3 by the Carter-Edwards in 10 trials. At the 500 yards' range, out of the 17 highest scores, 6 were made by the Soper in 9 trials; 5 with the Henry in 39 trials, and 4 with the Kerr in the Henry in 39 trials, and 4 with the Kerr in 25 trials; 1 with the Westley Richards in 6 trials; and 1 with the Carter-Edwards in 1 trial; thus showing that 16 out of 41 of the highest scores at 200 and 500 yards were made with the Soper rifle in 25 trials, in a contest where there were 265 trials and 17 different kinds of breech-loaders en-

gaged.
In November, 1867, it appears that 100 rounds were fired from this rifle in three minutes and one second, the first 40 rounds being fired in sixty seconds. The account of this trial having appeared in many of the public papers, the accuracy of the statement was doubted by many who read it. The inventor, therefore, in September, 1868, gave the public an opportunity of witnessing the extreme rapidity and certainty with which this rifle can be used, when fifty-two shots were actually fired, without a single missfire or hitch of any kind, in one minute, by Private Warwick, 1st Berks, the time being kept by Captain Stephens, 1st B.V.R., Adjutant Carter officiating as umpire. Under these circumstances, the Soper breech-loader is well

# THE APPLICATION OF SEWAGE

T the present time, local boards and other corporate authorities of our large cities and towns are upon the horns of a dilemma. It is imperative that they should find some means, or devise some method, of getting rid of their sewage. The rivers and streams—the old channels of outflow—are no longer available for this purpose. The legislature has for ever prevented the further pollution of the natural watercourses of the country. are no longer to act the part of open drains and sewers, to have their contents contaminated, and to empoison the air in their vicinity, by serving as receptacles for feecal matter and refuse of the most abominable description. What is to be done with it? is the question the bewildered authorities are asking themselves and each other. To our mind, this question admits of but one answer, and that is—apply it to the land. Although our experience in the actual application of sewage to land is limited in extent, yet we have the gratification of knowing that we are gaining fresh and reliable information every day upon this important subject. Moreover, the little that has been done is in its results of a most satisfactory and encouraging character. Therefore we repeat—apply the sewage to the land. Such has always been our view of a question which has been very carefully considered in a popular scientific brochure\* by Mr. Thomas Cargill, C.E., a copy of which is now before us. In this little work, the author details in a precise and methodical

\* "Sewage and its General Application to Grass, Cereal and Root Crops: showing the results obtained by actual experience down to the present date; with plans and sections illustrating the method of forming the ground for the different systems, and for distributing the sewage over irrigated fields." By THOMAS CARGILL, Civil Engineer, A.B.T.C.D., M.S.E. London: Robertson, Broorman, and Co., MECHANICS' MAGAZINE and Patent Office, 166, Fleet-street, E.C., 1869.

manner the various results that have attended the utilization of sewage. He demonstrates elearly that without indulging in extravagant anticipations, or allowing prejudice to run away with reason, there is every prospect of great material benefit and advantage arising from the proper treatment of the question. From past successes, limited though they be both in number and magnitude, there is a sure and reliable foundation for further operations; and Mr. Cargill asserts, and rightly, too, that there is no land so poor, so sterile, nor so exhausted, that it cannot be enriched, made fruitful, or refertilized, through the medium of sewage irrigation.

One special point upon which Mr. Cargill very judiciously insists is the fact that the farmer must call in the aid of engineering skill and ability to enable him to apply sewage with real profit to his land and his pocket. In furtherance of this view, and to indicate the absolute necessity of such a step, plans and sections are given illustrating the manner of forming the land for the purpose. glance is sufficient to assure any one that careful levels have to be taken in order to properly contour the land and ensure an equable distribution of the fertilizing fluid. As this important question becomes more fully ventilated, and more thoroughly understood in all its bearings, there is little doubt but that sewage engineering will assume a prominent position as a distinct branch of the profession. It is quite possible that the time will come when Mr. Cargill's views will be fulfilled, and we shall witness "sewage pipes laid on to the land for the use of the farmer and the agriculturist in the same manner as water and gas pipes are laid on for the supply of our cities and towns. We may add that the pamphlet is printed in a clear and readable type, and is very neatly got up, the plates being particularly striking. In view of the importance of the sewage question and the interest attaching to it at the present time, we cannot too strongly commend this little work to the notice of all interested in the matter. It presents a complete account of the reliable results that have attended the utilization of sewage, and brings the information down to the present time.

# ELECTRICITY AND TELEGRAPHY.

[ER Majesty's ship "Serpent" has commenced taking a series of deep sea soundings between Galle and Singapore, with a view to the laying of a submarine telegraph cable.

The cable for the Persian Gulf, in the "Tweed," has not yet left. The "Calcutta," after her serious accident, is to be repaired, and it is probable that she will be again on her way to Bombay-it is to be trusted this time without mishap. Measures will be immediately taken to recover the seventy miles of cable that were run out of her. To the wisdom and forethought of running this cable out, her safety was evidently due; the release of the great weight from her bows, and the natural buoyancy of the watertight tank (being thus emptied), contributed entirely to this result. There appears but little doubt of the drowning of the captain, but the safety of one boat's crew is still a matter of uncertainty.

The manufacture of the French Atlantic cable is steadily progressing at a rate of about 150 miles per week, and the coiling on board the "Great Eastern" is going on. The fitting up of the ship with the necessary cable machinery is being also proceeded with, and, when complete, she will be as nearly like the successful "Great Eastern" of 1866 as possible.

The British and Irish Magnetic Tolegraph Company have declared a dividend at the rate of 12 cent. per annum.

The British Indian Telegraph Company have already made the first step towards the energetic measures we anticipated. An order for the cable, according to the contract previously entered into,

Maintenance Company for the entire amount of cable, 3,600 nautical miles in length. The Maintenance Company are at present occupied with the manufacture of the French Atlantic cable, and on its completion the new Indian submarine line will be commenced, and be as rapidly proceeded with. There is no doubt whatever but that the line will be laid early in next year. These two orders amount to the large sum of over two millions, and will add 7,200 miles to our already extensive system of submarine cable.

A satisfactory half-yearly meeting of the Electric and International Telegraph Company has been held, and a dividend declared for the half-year of 5 per cent., and an additional dividend of 41 per cent. on account of back dividends; both of these are free from income-tax, and make the total dividend for the year 141 per cent. The remarkably healthy state of this company may be shown by the fact that their reserve fund now amounts to £136,000.

The directors inform us that the Post Office authorities have examined the company's books and plant, for the purpose of deciding the net profits for the year purchased, from July 1, 1867, to July 1, 1868. These examinations have been of a most searching and complete character, and have been regularly and systematically carried on. The value set upon the company's property by the directors has been carefully made out by professional accountants, and it is hoped that the arbitrators will soon take the matter into con-

The engineering reports are no less satisfactory, the land and submarine lines being in excellent repair. The amount expended in renewals and maintenance, by keeping the lines always in first-class condition, enables the company's system now to withstand almost any weather. Although the weather during the half-year had been very boisterous, but interruption had taken place on the land lines. Although the weather during the past but little

The engineer reports that "the English end of the older of the two Zandvoort cables has been renewed, and landed at Lowestoft, instead of at Dunwich. This alteration of route avoids a part of the sea bottom which has proved destructive to the iron sheath, and by bringing the end to a more accessible part of the coast, and to the same testing hut as the other Zandvoort cable, places it under the eye of the company's resident officer, and renders maintenance

more easy and less expensive."

Some years since, the item of maintenance of submarine cables was to have entirely disappeared from the company's accounts, but every half-year it is always to be found there, with but little varia-tion in the amount; this half-year it amounts to £2,305. This may be looked upon as the expense incurred by the usual submarine cable maintenance ship and staff, and by the repairs of the three break

On July 1, the North Lowestoft cable was broken and repaired eight days after.

On October 22, cable was damaged by an anchor, and repaired on July 27; this was done without interfering with the signalling.

On July 11, the Wexford cable was broken, and repaired on the 27th.

The extensions on land have been unimportant. A line has been erected from Inverness to Wick, and the new branches of the South-Western are being provided with telegraphs. The increased value of electricity, for purposes of signalling on railways, is shown by the erection of special signal wires between London and Bedford, on the Midland Railway, on the North Western, Great Western, and other railways.

A modification in batteries has been introduced by M. Ney. It consists of the ordinary copper and zinc elements, but placed in different solutions to the general variations of the Daniell cell. An amalgamated plate of zinc is placed in a vessel filled with a solution of chloride of ammonia; in this vessel is the porous cylinder, containing the copper plate, immersed in a solution of carbonate of copper. is contended for this battery that it is constant in action, and remains so for a length of time. It can be maintained for a great period in active operation, if the liquid ammonia be replenished; for this has been given to the Telegraph Construction and purpose, it is sufficient to drop in solid chloride of

smmonia. The natural carbonate of copperate used. It is suggested that if required for military purposes, or for any service requiring transport, or where the batteries are liable to be carried about, it is only necessary to use sand impregnated with a solution of chloride of ammonia, instead of the solution itself.

M. Joulin, who has been engaged extensively in the manufacture of gunpowder and saltpetre, has noticed the extraordinary fact that, by means of conducting rods, sufficient electricity can be obtained from pulleys, excited by the friction of straps travelling at considerable speed, as to produce electric "brushes." He considers it as an duce electric "brushes." He considers it as an element of some danger in a powder manufactory.

M. Roudet has been trying some experiments in his cyanide of potassium battery. He found that its magnetic force, as compared to a Bunsen, was as 81 to 93. The following results are also given by him:-

Bunsen			933
Chloride of potassium and chlori	hydra	ıte	
of ammonia	٠.		601
Marié-Davy			548
Daniell			384
Latimer Clark gives the following	, as t	he e	electro
notive force of batteries:-	•		
(1			100

Grove 100 98 Bunsen Marié-Davy . Daniell

The results are not strictly proportionate. A new form of battery was slightly noticed in our columns some time back as the invention of the Abbé Fortin, the principal difference being the substitution of a liquid smalgam of zinc for the ordinary amalgamated zine plate. A good deal of interest has lately been given to it in France as possessing great electrometive force and peculiar constancy. The following is a description of it: constancy. The following is a description of it:— The exterior jar having its lower part non-porous and well varnished, contains the liquid amalgam of zinc, above this it is principally porous. Contact is made with the zinc by a gutta-percha insulated wire, with its extremity bare; this end, immediately on entering the liquid amalgam, becomes amalgamated, and establishes a thoroughly good contact. Its upper end is bent round the exterior jar. The interior cell consists of a porous jar, not resting on amalgam, but supported by the upper edge of the outer vessel. Its porosity only extends to the lower half to prevent the exciting liquids mixing. The negative element in it consists of a copper plate, or a plate of lead, carbon, platinum, or any platinized metal; the exciting liquid depending upon the metal, being either sulphate of copper or salts of lead, mercury, silver, &c. The exterior vessel is charged with dilute sulphuric acid. By means of the porous portion of the outer vessel, the sulphate of zinc is eliminated. It attaches itself to the side of the vessel, and, either by filtration or efflorescence after the evaporation of the water, forms on the outside, and can be scraped off. All local action in this battery is done away with, and, although at first the extra expense of the mercury may appear a disadvantage, it is contended that by producing a more powerful and constant and a less expensive battery in action, this extra cost is counterbalanced. At present we are unaware of any practical trial being given to this form of

OTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-NOTES PLICATIONS.

PROMOTERS OF VAPOURIZATION—A NEW FACT IN THE BEHAVIOUR OF IRON—SUBSTITUTES FOR

VERY interesting communication made to the A Royal Society by Mr. C. Tomlinson mentions some facts which suggest a wide practical application. Anyone who has observed a liquid boiling in a glass vessel, will have noticed that the bubbles of vapour start from but a few points, sometimes, indeed, from only one. It is not because that spot is hotter than surrounding parts, but in most cases, a minute speck or point may be seen either in the glass itself or adhering to it, and from this the bubbles of vapour stream away. Mr. Tomlinson regards a liquid at or near its boiling point as a supersaturated solution of its own vapour; and just as in supersaturated saline solutions, the introduction of a solid nucleus starts crystallization. so in the present case, the solid nucleus serves to

start ebullition. On one condition, however, the point, or speck, or nucleus, must not be "chemically clean." Chemical cleanliness, we need hardly say, means absolute cleanliness. Many may suppose, means absolute cleanliness. Many may suppose, that when, for instance, they have washed a glass rod in water and wiped it with a clean cloth, the rod is clean. Not at all; it may be dirtier than it was before. To get it chemically clean, you must put it in strong acid, then rinse it with distilled water, then put it in ether, and finally wipe it, as we may say, with the flame of a spirit lamp. Then for a moment, you may have it clean, but only for a moment; one wave in the air and it is chemically unclean once more. Dirt, however, we know is a very useful thing when in the right place, and some things which we have to regard chemically some things which we have to regard chemically as dirty, and which indeed refuse to be made clean, are highly useful as "promoters of vapourization," an expression of Faraday's adopted by Mr. Tomlinson. Among these coke and charcoal are the most active, and the results of some experiments made for Mr. Tomlinson suggest the introduction of a bushel or two of one of them into every steam boiler. Thus when water was boiled for twenty minutes in a class flesh alone 905 grains for twenty minutes in a glass flask alone, 995 grains boiled away, but when some pieces of coke were added, 1,130 grains of water boiled away in the same time. An experiment with wood charcoal had more striking results. Water was made to distil freely from a still, and the quantity collected in fifteen minutes was weighed. Some pieces of charcoal were then added, and the distillate again collected during the fifteen minutes. From the water alone, 262 grains were collected; from the water with charcoal, 334 grains; that is, upwards of one-fourth more water was evaporated when the char-These experiments were made coal was used. under the ordinary pressure, and it is likely that the results under extraordinary pressure will be An incidental advantage will be that still better. the coke or charcoal will prevent, to a great extent the deposition of crust on the bottom of the boiler, and so prevent a waste of heat from that source.

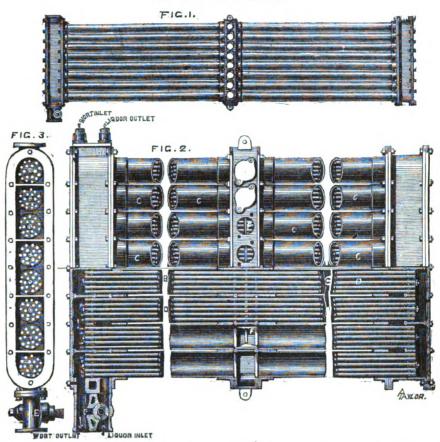

Mr. Gore has noticed a new fact in the behaviour of iron under the influence of heat and strain. A strained iron wire was heated to redness by a current of voltaic electricity, and then the current being discontinued, was allowed to cool. It was observed that there arrived a moment in the process of cooling at which the wire sud-denly elongated, and then gradually shortened, until it became perfectly cold, remaining howuntil it became perfectly cold, remaining however permanently elongated. No other metal besides iron exhibited this peculiarity, which Mr. Gore attributes to a momentary molecular change; and he points out that this change would probably happen in large masses of wrought iron, and would come into operation in various cases where those masses are subjected to the conjoint influence of heat and strain, as in various engineering operations, the destruction of buildings by fire, and other cases. The since every fact relating to iron is of importance

It is very hard in these days to hit upon an absolute novelty. Dr. Sace probably thinks he has done so, when he proposes to the French Academy of Sciences the use of tungstate of baryta in place of white lead. In fact, several tungstates were suggested for the purpose some years ago, and tungstate of lead was used to a considerable extent. Its price, however, was an years ago, and tungstate of lead was used to a considerable extent. Its price, however, was an obstacle to its general employment. All lead compounds, too, are open to the objection of becoming discoloured by the action of sulphuretted hydrogen, and the tungstate formed no exception. One difficulty with baryta is to get a tungstate which will retain a pure white colour when thoroughly dried; and, if this be exercuse, the colour does not cover well because colour when thoroughly dried; and, if this be overcome, the colour does not cover well, because of the crystalline character of the precipitated salt. Tungstate of baryta is formed by precipitating tungstate of soda with chloride of barium, and it is said to exhibit in an eminent degree the phenomena of fluorescence. If any but the monotungstate of soda be employed, the precipitate, when dried, is more or less yellow. Wolfram is now much cheaper than it used to be, and a further investigation of the tungstates as pigments might meet with some reward.

It is officially intimated that Peruvian guano has been found at thirty-five places on the main land and islands of Peru, independent of the other localities well known before. Accurate surveys are ordered, as in the case of the Maccabe, Gunape, and Lobos. One place is estimated to contain 3,000,000 tons, situated near the River Loar.

# REFRIGERATING APPARATUS.

BY MR. T. WILKINS.

BREWING PLANT AND WILKINS' MACHINERY.

INDER the above comprehensive head, we purpose to notice some fell pose to notice some of the special productions of Mr. Thomas Wilkins, of the Orchard Works, Ipswich. These works have long been renowned for the machinery turned out there, which is of a plain and unadorned, but thoroughly substantial character. We will first describe the apparatus to which our engravings refer, and then proceed to notice several other important adjuncts of the brewery. The mashing machine is Chittenden's patent, and is manufactured by Mr. Wilkins. This machine is on a new principle, and is found to be superior to other systems. It quickly and thoroughly saturates and mashes every particle of grist before falling

into the tun. It can be used while the covers are on the tun, thus preventing the loss of heat and flour. Being self-acting, it requires no motive power beyond the supply of liquor used for the mash. The operation is as follows:—When proceeding to mash, the liquor is turned on, and enters the small cylinder beneath the cone, where it comes into contact with a water-wheel contained within it. The wheel is attached to the rakes, and therefore sets them in motion. The liquor escapes down the three pipes shown in section, which are

perforated only on one side, in the same way as ordinary sponge, and is thence transmitted to the falling mait. Owing to the arrangement of liquor, all its force is utilized, and a powerful turbine is produced. The malt falling from the hopper on to the cone is thus equally spread over the machine, and is thoroughly mixed with the liquor escaping from the revolving rakes, and the mash is perfect.

We next come to Mr. Wilkins' refrigerator, which was introduced by him some thirty years since, and which has been the subject of repeated improve-ments, bringing it to a state of high efficiency. Our engravings represent a twenty barrel refrigerator, of which fig. 1 is an elevation, fig. 2 an end view with the cover removed, and fig. 3 sections of the various parts. The liquor entering the large pipe c, surrounds the small pipes b, which contain the wort, and, passing from end to end of the large pipes, successively, makes its exit almost as hot as the boiling wort enters. The wort enters at the same end of the refrigerator that the liquor escapes from and passes through the small pipes, of which there are seventeen in each of the large pipes, thus meeting the colder liquor as it cools, until it escapes within 6deg. or 7deg. of the temperature of the cold liquor. With this apparatus no coolers are required, as the wort can be admitted direct from the hop-back, using fron  $1_{\frac{1}{6}}$  to 2 barrels of liquor per barrel of wort. Referring to the details of construction, we may observe that a are discs, two of metal and one of india-rubber between them. The outside of these discs fit the insides of the pipes c, while the holes in them fit the outsides of the pipes b. A bolt, d, passes from end to end of the refrigerator, and compresses the india-rubber at each end between the discs, thus making a perfeetly tight joint between liquor and wort. At the same time the apparatus is easy of access for repairs to the small tubes. e is a two-way cock, which, when the worts are down (the cock leading to the fermenting squares being closed) is opened, and liquor pumped through the wort-ways into the hop back thus thoroughly cleansing the insides of the small pipes; f is a stay in the centre box, which supports the small tubes and keeps them apart from other. The efficiency of this refrigerator is admitted wherever it has been introduced. Some of the original ones are in the places where they were

work, and is very suitable for brewers. To twenty quarters it comes out about half the price of highly-finished engines, and works just as well. Several working of these engines of 4-horse power are of these engines of 4-norse power are working 15-quarter broweries, pumping liquor, worts, &c., mashing, grinding malt, hoisting sacks, and doing stable work besides. Mr. Wilkins has a very good stop valve, which he calls the "straightway," and which is better for use than that of ordinary form, which usually prevent the pipes being emptiod of their contents. There is no obstruction to the free flow of the passing fluid, so that pipes can be emptied without separate drain cocks, a great desideratum in breweries. The valve is regulated by a screw turned by hand wheel, which is the best method out. A three-throw pump of Mr. Wilkins is worthy of notice, as being very neat in design, and as having a very long stroke, and being design, and as naving a very long stroke, and being of great strength and durability. On the whole, having examined the make and arrangement of Mr. Wilkins' machines, we can commend them to our brewing friends, not as highly-finished examples, but as specimens of sound design and good substantial workmanship, and as bearing the stamp of utility with economy.

#### WIRE ROPE TRANSPORT SYSTEM.

A NOVEL use of wire ropes has recently been patented and put into practice by Mr. Hodgson, C.E., having for its object the construction of light and cheap ways for the transport of mineral or agricultural produce in localities as yet unprovided with railways. Though a great number of cases exist in Great Britain to which it may be applied with advantage, the chief development of this method of carriage will probably take place in the colonies, and in other countries which stand in urgent need of light lines of some kind to convey their productions to the main arteries of inland communication, or to ports. The system may briefly be defined as a continuous development of the plan now not unusual in India, Australia, and in some mining districts, of bridging over a river or ravine by a single wire rope, by which, carried in a bucket suspended by a pulley, the necessary loads are transmitted from one point to another.

To accomplish the easy passing of the points of support necessary to carry out a continuous line of communication, and to provide for the distribution of the burden and the application of motive power, have been problems of no small difficulty; but, after experiments on a first trial length of half a mile, during the autumn of last year, these practical details were worked out, and a contract was immediately entered into for a line of three miles in length at Bardon Hill quarries, belonging to Messrs. Ellis and Everard, near Leicester, which has recently been completed, for mineral traffic. The practical working of this line was tested last Saturday, in the presence of a number of ongineers and gentlemen interested in the question, when it was found to work well, and to answer its purpose admirably. This line consists of when it was found to work won, and we amount its purpose admirably. This line consists of an endless wire rope, supported on a series of pulleys carried by substantial posts, which are ordinarily about 150ft. apart, but, where necessary, much longer spans are taken, in one case amounting to nearly 600ft. This rope passes there of its ands round a Fowler's clip drum, at one of its ends round a Fowler's clip drum worked by an ordinary portable steam engine, and the rope is thus driven at a speed of from four to six miles an hour. The boxes in which the stone is carried are hung on to the rope at the loading as carried are hung on to the rope at the loading end, the attachment consisting of a pendant of peculiar shape, which maintains the load in perfect equilibrium, and at the same time enables it to pass the supporting pulleys with ease.

Each of these boxes carries 1 cwt. of stone, and the delivery is at the rate of about 200 boxes or ten tons per hour for the three mile distance. It

is almost unnecessary to observe that the proportions of such lines can be varied to any extent to suit the requirements of any particular trade, ranging from 10 tons to 1,000 tons per day.

In the case of lines for heavy traffic, where a series of loads, necessarily not less than 5 cwt. to

10 cwt. each, must be carried, a pair of stationary supporting ropes, with an endless running rope for the motive power, will be employed, but the method of supporting, and the peculiar advantage of crossing almost any nature of country with a goods line without much more engineering work

vary considerably in proportion to the quantity they are required to carry, but from their peculiar con-struction their cost will vary very slightly in relation to the nature of the ground which they may traverse.

The most important feature in Mr. Hodgson's invention is his method of passing the points of support. Both in lines like that now in operation, where the rope moves, and in those in which it is proposed to have a standing rope separate from the propeller, the stability of the load is obtained by curving in the frame of the carriage till the centre of gravity comes under the rope. The overhanging of the rope is of course ossential in this case. Nothing can be more satisfactory than the working of the present three mile line, which stamps it as a practical invention, and which we hope will lead to its adoption wherever the necessity for such an appliance exists.

## LONDON ASSOCIATION OF FOREMEN ENGINEERS.

ON Saturday last the sixteenth anniversary of the above Association was celebrated in the usual way by a dinner at the City Terminus Hotel, Cannon-street. Mr. Joshua Field, Esq., C.E., Hotel, Cannon-street. Mr. Joshua Field, Esq., C.E., occupied the chair, and Mr. R. Moreland, Esq., C.E., the vice chair. The members and guests numbered nearly 200, and amongst the company present we observed General Lefroy, R.A., F.R.S., E. J. Reed, Esq., C.B., Joseph Whitworth, Esq., LL.D., F.R.S. W. Todd, Esq., C.E., Robert Mallet, Esq., C.E., F.R.S., Frank Ives Scudamore, Esq., Henry J. Slack, Esq., F.G.S., Captain Rintoul, Edward R. Allfrey, Esq., C.E., Edward Humphrys, Esq., C.E., John Penn, jun., Esq., Charles Seidler, Esq., Jchn R. Ravenhill, Esq., C.E., James Robertson, Esq., V. Pendred, Esq., Passmore Edwards, Esq., Dr. Fennell, &c.

After the usual loyal toasts, the Chairman proposed that of the "Army, Navy, Militia, and Volunteers," which was responded to by General Lefroy, and Mr. E. J. Reed, C.B., the Chief Constructor of the Navy, Captain Monoriefi, who was also to have responded, being absent from illness. The report of the secretary, Mr. D. Walker, was then read, after which "Prosperity to the Association" was proposed by the Chairman, who coupled with the toast the nave of its indefitigable president. the toast the name of its indefatigable president, Mr. Joseph Newton. Mr. Newton, in responding, very happily referred to the relations between the foremen engineers and their employers, and pointed out the good feeling and perfect under-standing which existed between them. He also referred to the satisfactory condition of the Association, which was due in some respects to the employers as well as to the members themselves. Other toasts of a complimentary character were given, and, with musical selections, served to interest the company until about twelve o'clock, when the meeting separated, after an exceedingly

pleasant evening. Our readers and the public generally are, for the most part, well aware of the nature and objects of this Institution; but as there are always some who desire information on such matters, we think the present occasion a fitting one to say a few words explanatory of the origin and objects of the Association. It was founded in 1852 by a few zealous and intelligent foremen, who felt that the class to which they belonged occupied, intellectually and socially, an isolated and unsatisfactory position. They, therefore, at once proceeded to frame a set of rules, and to constitute themselves a socioty. They struggled on through good report and evil report for some years, and having weathered the storm, the London Association of Foremen Engineers is now in vigorous health, and exhibits no symptoms of decadence. Each year witnesses a steady accession to its list of honorary Each year and ordinary members. The first-named class comprises some of the most eminent employers of engineering labour in the metropolis, and many gentlemen distinguished for their scientific acquirements and high social position. The second are drawn from the ranks of foremen and draughtsmen connected with the various branches of the engineering trade, and who are only eligible after having occupied principal posts for the space

of two consecutive years.

The operations of the Association are conducted on two distinct bases—the one scientific and the other benevolent. It has its monthly meetings for the discussion of practical subjects, its library of

blished. The first of these has reference to the temporary assistance of unemployed members, and is maintained exclusively by the annual subscriptions of ordinary associates. The second, for the payment of a certain sum on the death of a member, is maintained from the same source. The third fund is that for partially maintaining old, decayed, and worn-out foremen, who have been members, and who are unable wholly to sustain themselves. This is known as the superannuation fund, and it is almost exclusively the creation of the employers and other honorary members of the Association.

Having glanced at the origin and objects of the Association, let us now turn to its present position, which is represented in the following extracts from the sixteenth annual report, which was read by the secretary upon the present occasion. document records a continuance of the steady progress of former years; while the established features of the Association have worked steadily and well, new ground has been opened and fresh enterprise entered upon. Ten ordinary and seven honorary members have been added during the year, and two deaths have occurred, the effective number being 104 ordinary and 67 honorary members. The income of the past year was £221 10s. 6d., whilst the expenditure was £261 14s. 9d. These figures show the expenditure to have been £40 4s. 3d in excess of the income, the effect of the severe commercial panic, which necessituted payments to a number of unemployed members. The present value of ordinary funds invested in stock Three per Cent. Consols is £364 4s. 2d.; there is in the savings bank the sum of £65, and in the treasurer's hands £4 18s. 9d., making a total of £434 2s. 11d. A widow and orphans' fund was established in the early part of the past year, which has not progressed quite so satisfactorily as could have been wished. To the superannuation fund there has wished. To the superannuation fund there has been subscribed by the various gentlemen a total of £95 14s., which, with subscriptions previously acknowledged, gives £720 18s. The interest on this sum is £51 16s. 2d., giving a grand total of £1,044 16s. 2d. We are glad to learn that this fund, with the accumulating interest, remains intact, no application having yet been made for the benefit it provides, although when applicants do come forward, the amount will go but a short way in providing for them, as the interest—the only part that will be appropriated—would suffice for but two at the rate laid down. The interest in the proceedings of the monthly meetings-of which abstracts appear in our columns—continues to increase, and they are found to improve in usefulness as the papers become more practical and less speculative; in fact, in every department of this Association there are evident tokens of advancement and steady progress, which must, by improving the intellectual and social condition of the foremen engineers, act beneficially upon the interests of the employers of engineering skilled labour.

# COILED TUBE BOILERS.

T was once thought that the perfection of boiler construction had been arrived at in boilers made on the coiled tubular system. This principle, however, soon showed a radical defect which led to its abandonment. Boilers so constructed failed on account of the tubing becoming red hot when the engine was standing, and the force pump was consequently not acting. This defect, however, has been practically overcome by Mr. Thomas Mills, of No. 2, Crescent-road, Plumstead, in the invention we are about to describe. Mr. Mills constructs the firebox of a boiler, of the upright form, of a coil of tubing enclosed in a case, the firebox being contained within the coil. The bottom of the coil is connected by a tube brought down outside the casing from the upper part of the boiler, at the lower end of which tube is fixed a self-acting valve placed in a horizontal position, which allows the water to pass on into the coil. The expansion of the water caused by its coming in contact with the heated tubing closes the valve after it has passed through it, and thereby prevents a backward flow of water through the outside tube, and forces the water and steam on through the coil into the upper part of the boiler again. After this, the valve again opens, in con-sequence of the downward force of the water in the outside tube, thereby creating a perfect circula-tion through the coil, the discharge end of the coil being brought up inside through the bottom of than is necessary for fixing an electric telegraph, without bridges, without embankments, and without masonry, exists equally in both branches of the system. The cost of establishing these lines will

Google Digitized by

the pump being altered according to the quantity of water required to supply the boiler), and cutting off the other supply of water by means of a cock fixed in the outside tube connecting the upper part of the boiler with the lower end of the coil, thereby feeding the boiler with water through the coil without in the least degree reducing the volume of steam. This method of feeding the coil by the outside tube and valve brings the water direct into the hottest part of the coil, and keeps up a perfect and continuous circulation without the aid of the force pump. This pump is used to feed the boiler through the coil, which is a great advantage in itself, as the cold water does not come into direct contact with the steam contained in the upper part of the boiler, which causes loss of steam by condensation. Mr. Mills has made practical trials of this improved system of construction, and finds it to realize the following advantages—economy in every respect, rapid generation of steam, great strength, and almost entire freedom from explosion, together with lightness and simplicity. He states that it raises stoam from cold water in less time than any other boiler at present in use. The cir-culation through the coil being exceedingly rapid, no deposit is found to remain in it. The self-acting walve or clack is so simple in construction that it cannot fail to act.

#### ROYAL UNITED SERVICE INSTITUTION.

A T the evening meeting of the members of the above Institution, on Monday last, Admiral Sir Henry Codrington in the chair, Mr. J. M. Hyde read an able paper "On Deflecting Armourplated Ships for Coast Defence." The lecture was illustrated by two admirable models, and a series The lecture was of experiments made with model gun, shot, and targets, all alike on a scale of one inch to a foot; the model 600-pounder having thus a bore of exactly one inch, and the six, nine, and twelveinch targets being equally represented by halfinch, three-quarter-inch, and one-inch plates.

The system of plating shown in Mr. Hyde's models may be regarded as an iron glacis at a slope of 221 degrees around the entire deck; the one model having plated chambers at each end, bow and stern, the other having a plated casemate in the centre. The armour forms an overhanging knuckle all round the ship, the horizontal edge of which is the only portion facing directly the line of fire from an enemy's guns, and this portion presenting with 4in. armour-plating a depth of I8in. to the enemy's projectiles. The series of experiments with the model gun and targets were exceedingly interesting, as showing the defensive value of angulated armour, and remarkable deflections of shot with ogival heads, particularly so when a wood facing was placed in front of the iron armour, the shot in this case turning out again by ricochet without touching the plate itself. A plan for the conversion of wooden ships by the addition of Mr. Hyde's armoured sponsons was also submitted. In Mr. Hyde's system, it will be understood, the ship has no vertical wall whatever. The paper was discussed by Captain Beamish, Mr. Wilson, and other gentlemen, the chairman expressing a high opinion of the value of deflecting armour for ships of war.

## THE FOREIGN COAL AND IRON TRADES.

THE demand for coal in Belgium has somewhat improved, but the trade is still characterized by a certain hesitation, and in the basin of the Couchant de Mons the production has been reduced to one-fourth its full amount. The coalowners of the province of Namur have formed an association for the protection of their trade interests. It is calculated, but unofficially, that the total quantity of coal exported from Belgium to France last year was 3,226,378 tons, as compared with 3,014,452 tons in 1867, and 3,393,649 The quantity of coke exported from tons in 1866. Belgium to France last year was 193,131 tons, as compared with 232,984 tons in 1867, and 292,793 tons in 1866. A readjudication of a contract for 9,000 tons of rails required for the Belgian State railways will shortly be made, but the date has not yet been fixed. Some improvement is noted in pig in Belgium; refining now ranges from £2 16s. to £2 18s. per ton. Stocks of pig are stated to be generally much reduced in Belgium, while the requirements of consumption are increasing. The demand for pig is also active in the French department of the Moselle, and the French iron trade generally may be said to sustain the im-provement which has been noticed in it of late.

THE CLYDE AND NEW YORK, 1868.

THE returns of the shipping trade between the 1 Clyde ports and New York during 1868 show a marked increase of prosperity over those of the preceding years, both as regards outward and Over 1867, which was an excepinward trade. tionally prosperous year, there was an increase last year in the sailings from the Clyde of 3 vessels and 4,250 tons, but only an increase in the arrivals of 6 tons, the number of vessels being less by two than in the previous year. Over 1866, however, the increase in arrivals amounted to 18 vessels and 17,000 tons, and in sailings to 15 vessels and 16,600 tons; while over 1865 the increase in arrivals amounted to no less than 32 vessels and 42,000 tons, and in sailings to 42 vessels and 45,200 tons. The number of vessels which left the Clyde last year for New York was 73, and the tonnage 77,752, and the number which arrived 64, and the tonnage 72,058—a trade rather more than double that of four years ago. Besides this, an active trade has been carried on between the and other North American ports. Clyde arrivals there were six steamers and seven sailing ships of 7,015 tons from New Brunswick; 21 vessels, of 3,038 tons, from Newfoundland; 13 ships, of 5.418 tons, from Nova Scotia: 5 vessels of 1,054 tons, from Prince Edward Island; and 16 vessels, of 8,948 tons, from United States' ports other than New York. There sailed 34 vessels of 5,963 tons; for Newfoundland; 10, of 6,446 tons. for St. John's New Brunswick; 19, of 8,780 tons, for Nova Scotia; 10, of 4,373 tons, for Boston; and 25, of 17,378 tons, to other United States

#### THE RECENT HEAVY STORMS.

OUR readers are doubtless often struck by paragraphs in the daily graphs in the daily papers narrating the bravery of the crews of the lifeboats which are happily increasing in number every year. The frequent repetition of these tales of disaster and rescue must have convinced the least thoughtful that a large amount of noble work was being effected. But the extent is not easily realized until the aggregate sum is shown, which is only done at the meetings of the Royal National Life-boat Institution. With the view, therefore, of promoting the interests of this noble service. ask our readers to go with us through the following summary of the business transacted at the last of the Institution, which was held at its meeting house, John-street, Adelphi, London, Thomas Chapman, Esq., F.R.S., V.P., in the chair, when rewards amounting to £78 were ordered to be given to the crows of the following lifeboats of the Society for their gallant services during the late storms. The Teignmouth lifeboat "China" saved the crew of four men of the trawler "Start," of Brixham, during a gale of wind on the 5th ult. lifeboat "Albert Edward" saved the crew of six men of the brigantine "Thomas," of Poole, eight men from a small boat which had capsized in endeavouring to rescue them, and the crew of six men of the French schooner "Alexandrine," of Pornic, all of which, during a strong gale from W.N.W., with a heavy sea, were wrecked on the Doomed Bar on 15th ult. In rescuing the crew of the French schooner, the lifeboat shipped two heavy seas and lost two oars. The Southwold large sailing lifeboat had also gone off, and saved the master and three of the crew of the barque "Lord Coke," of Middlesborough, which had sunk on Sizewell Bank during squally and thick weather on the 15th ult. The Lowestoft lifeboat "Lætitia" had likewise gone off during a gale of wind and rescued the crew of eight men of the sloop "Queen of the Tyne," which was wrecked on Corton Sand, on the 29th ult. The Great Yarmouth lifeboat "Mark Lane" had put off and saved the crew of thirteen men and a pilot from the barque "Libertas," of Genoa, on the 31st ult. The Cadgwith lifeboat "Western Commercial Traveller" had also, with the assistance of two steamers, brought into Falmouth the Austrian brig "Veritas," and three French fishermen who were on board the vessel, which was in a disabled state, had been abandoned by the crew and was likely to drive on the Manacles Rocks during a gale of wind on the 29th ult. The Ramsgate lifeboat "Bradford" had also put off and rescued seven men from the schooner "Chaften Winkle," of Aalborg, which was wrecked, during a strong gale from S.E., at the back of the Goodwin Sands, on the 14th ult. The same lifeboat had also saved seven men belonging to the brig " of Rostock, on the 24th ult., making a total of sixty

given to the crews of the lifeboats of the Institution Braunton, Ballycotton, Mullion, Anstruther, Walmer, Dungeness, Thorpeness, Skegness, Mun-desley, and other places, for either assembling or putting off in reply to signals of distress, with the view of saving life from shipwreck.

The silver medal of the Institution, a copy of the ote inscribed on vellum, and £3 were voted to Mr. James Crowden, chief officer of coastguard at Muchals, N.B.; £2 to Robert Fife; and £1 each to five other men, for putting off in a coble, at much risk, and saving, in a gale of wind, four men from the schooner "Kinloss," of Aberdeen, which was wrecked off Scatraw fishing creek on the 21st ult. An effort had been previously made to communi-cate with the vessel by means of a rope, in which service Mr. Crowden received a severe contusion on the knee, being struck by a heavy sea, and dashed amongst the rocks. Various other rewards were likewise granted to the crews of different shoreboats for saving life from wrecks on our coasts. It was reported that the London coal merchants had prosented £703 10s. to the Society, to defray the cost of the Southwold large sailing lifeboat, which was hereafter to be named the "London Coal Exand that the merchants of Mincing-lane had given £1.000 to meet the whole expense of the Montrose lifeboat and its support. The ladies of Edinburgh had also, by means of a bazaar and collections, raised £1,000 towards the expense of the permanent maintenance of the "Edinburgh Workmen's" lifeboat stationed at Port Logan, N.B. A grand bazaar and fêtes are to be held at Exeter during Easter next in aid of the support of the twenty-two lifeboats on the coasts of Devon and Cornwall. Articles for sale at the bazaar are earnestly invited and will be thankfully received by the hon. secretaries at Exeter. It was decided to form a lifeboat station as soon as practicable on the Isle of Arran, N.B. Legacies amounting altogether to £600, less duty, &c., had been received from the executors of the late Mrs. and Miss Warner, of Lyncombe, Somerset. A first instalment of £100 had likewise been made to the Society on account of the legacy of the late C. W. Jones, Esq., of Norwich. The late J. S. Beckett, Esq., of Tormoham, Devon, had bequeathed £600 to for a lifeboat to be named the "Gertrude." ments amounting £1,700 were ordered to be made on various lifeboat establishments. New lifeboats had been sent during the past month to Weymouth, and to Lynmouth, North Devon. Demonstrations had taken place at each station to welcome the arrival and first launch of the lifeboats, that at Weymouth being of a most imposing character. A public meeting was recently held at Penzance, to present the rewards granted to the crews of that lifeboat and others, for their gallant services on December 6 last, in saving eight men from the wrecked barque "North Britain," of Southampton. The meeting, which was held in St. John's Hall, was one of the largest and most enthusiastic ever held in that town. A report was read from Captain D. Robertson, R.N., the Assistant-Inspector of Lifeboats to the Institution, on his recent visits to different lifeboat stations. The proceedings then

THE number of visitors to the South Kensington The number of visitors to the South Kensington Museum during the week ending February 13, 1869, was—on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 13,380; Meyrick and other galleries, 2.305; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,748; Meyrick and other galleries, 240; total—17,673. Average of corresponding week in former years, 10,489. Total from opening of Museum—8,154,430.

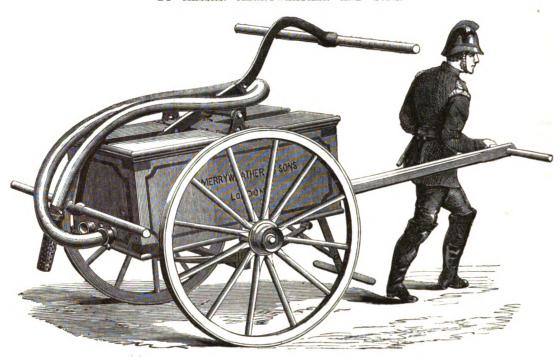

The number of visitors to the Patent Office Museum, South Kensington, for the week ending February 13, was 4,482. Total number since the opening of the Museum, free daily (May 12, 1858),

THE MANUFACTURE OF WATCHES AND CLOCKS THE MANUFACTURE OF WATCHES AND CLOCKS

A most interesting and instructive little work
describing briefly, but with great clearness, the rise
and progress of watch and clock making, has just
been published by Mr. J. W. Benson, of 25, Old
Bond-street, 99, Westbourne-grove, and the City
Steam Factory, 58 and 60, Ludgate-hill. The book,
which is profusely illustrated, gives a full description of the various kinds of watches and clocks,
with their prices and monophold racks a nucleus. with their prices, and no one should make a purchase without visiting the above establishments or consultwithout visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, who holds the appointment to the Prince of Wales, sends this pamphlet to any address on receipt of two postsix lives saved by lifeboats during the past month age stamps, and we cannot too strongly recommend alone. Rewards amounting to £115 7s. were also it to the notice of the intending purchaser.—| ADVT. |

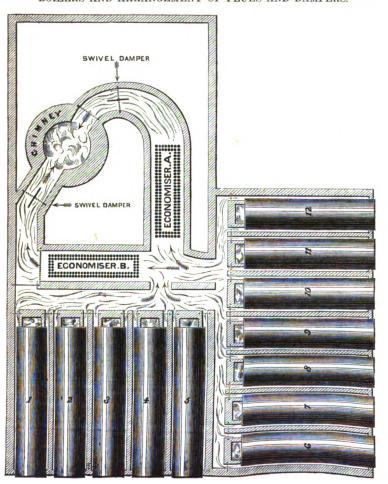

# CURRICLE FIRE ENGINE.

# FEED WATER HEATER EXPLOSIONS.

EPLAN SHOWING EXPLODED ECONOMIZER, WITH POSITION OF BOILERS AND ARRANGEMENT OF FLUES AND DAMPERS.

PLAN OF SHUTTING OFF ECONOMIZER TO BE AVOIDED.

N THE INFLUENCE OF THE OXIDES OF CHROMIUM AND TITANIUM
THE COMPOSITION OF PIG IRON.

THE Messrs Hayes, of 20, State-street, Boston, assayers to the State of Massachusetts, publish the following regarding the changes going on in the ore beds:—Within the last five years we have been frequently employed in chemical investigations of the altered character of some pig irons, which resulted, apparently under the usual circumstances, in the reduction of uniform ore. cases, the amount of carbon, united with iron, had been diminished, without the introduction of other matter, in quantity sufficient to influence a change in this connection, and generally no variation in the composition of the ore was known or suspected. We had analyzed the ores in some of the beds, in former years, and regarded them as well adapted to the production of pig iron of good quality; but, in pursuing the research, we were convinced that the change in quality of iron could be traced to altered composition in the ore of part of the beds used for supplying the furnaces. The correctness of this view was confirmed by our analysis of many iron ores, in some of which we found the oxides of chromium or titanium existing where they were not indicated, or connected with the ore in beds, which have been considered as pure iron ores. But the exide of chromium and the oxide of titanium seem to act in the furnace or crucible in a way to withdraw a portion of the carbon, or prevent that true union of carbon, with a portion of the iron, which constitutes grey pig iron, without the metals of these oxides really alloying with the iron, and thus indicating the cause of the change. We have analyzed samples of pig iron, where these oxides accompanied the ores in the beds, but we were not prepared to find an influence exerted on the quality of the pig metal without the refractory metals forming a part of the composition.

The occurrence of oxide of manganese with iron

ore is common, and titanium compounds are often found in both magnetic and brown iron ores as insoluble substance, in small proportions, and these compounds combine with, and are removed by, the grace without injury to the pig metal. These fluxes, without injury to the pig metal. These compounds of titanium are the cause of the often superb blue colour of the cinder, produced under varying conditions, of glassy or stony character, and must be carefully distinguished from those we regard as more detrimental in their influence on the metal. In a number of analysis of iron ores, we had found both oxide of chromium and oxide of titanium, in a state rendering them soluble in diluted acids, and in condition to escape detection in the ordinary modes of analysis. Both magnetic and brown iron ores have been found to contain either oxide of chromium or oxide of titanium in this soluble state. Among the samples from con-tiguous beds, this diversity in composition, made the presence of some oxide of chromium, or oxide of titanium existed—and while the bulk of a bed of ore was pure, continuations of the bed, or associated ore, yielded notable weights of oxide of chromium, or oxide of titanium, in the different samples. The suggestion we would make to the iron master in view of these facts is, the possibility that the quality of the pig metals, in anomalous cases, being greatly influenced by the admixture containing the oxides of chromium or of some ore titanium, with the basis ore of good quality. This may take place by the main bed being crossed by veins of mixed ore, or by the workings passing into contiguous beds, where one kind of ore is used. In other cases, where the iron master can gain the greater advantage arising from mixing ores the kinds may contain contaminating oxides, and injure the iron. The following are some results of analyses, showing the proportions of oxide of chromium to the metallic iron contained in the ores :- 1st. Magnetic ore.-Iron, 49; oxide chromium, 1.40. 2nd. hematite ore.—Iron, 42.47 oxide of chromium, 1-60. 3rd. Brown ore.—Iron, 54-32; oxide of chromium, 1-90. 3rd. Brown massive —Iron, 46.70; oxide of chromium, 1-04. Mere traces have been discovered in some cases, while in other instances a larger proportion of chromium formed an alloy with the iron produced from the ore

# CURRICLE FIRE ENGINE.

THE accompanying illustration shows an improved curricle fire engine made by Messrs.

Merryweather and Sons, of London. These engines have each a pair of gun-metal pumps, 4in. diameter, with 9in. stroke of pistons, and, when pumped by six men, are capable of discharging sixty gallons per minute to a distance of 80ft.

The pistons, valves, and seatings are also of gun motal, fitted into a chamber, wherein they are most easy of access. The air vessel is of copper, whilst the frames, working levers, axle, &c., are of wrought iron. The works are mounted in a strong oak cistern, which may be supplied with water by means of buckets, when the engine is not working through its suction pipe. This cistorn has a pair of covers, and the hose is preserved there. The suction hose, as will be noticed upon referring to the illustration, is always affixed to the suction screw of the engine, so that, by the unbuckling of a single strap, and connecting a delivery hose, the engine may be put into action in a few seconds. Being mounted on high wheels, it is easily and rapidly drawn by one man through The cost of an engine of this class is the streets. The cost of an engine of this class is considerably lower than that of the ordinary fire engine, whilst, at the same time, it is equally efficient. Many of them are in use in Spain. They are also adopted by the Metropolitan Fire Brigade, as also in country villages, and the mansions of the nobility and gentry.

#### FEED WATER HEATER EXPLOSIONS.

REED water heaters, or fuel economizers, have for some time past, been in extensive use, and until quite recently they have always been considered as absolutely safe. It has been thought that the failure of one pipe could not possibly lead to the failure of others, but that the pressure would be eased off and explosion rendered im-possible; that, in fact, a cracked pipe would only be a safety valve. This opinion is generally enter-tained with regard to the various tubular boilers now before the public, and so far there has been no reason to question that opinion as regards the boilers. But the explosion of a feed water heater some twelve months since, at Blackburn, of another at Preston, in October, last year, and of a third at Lille, still later, by which three persons were killed, renders the subject of safety in this form of construction one of considerable importance The occurrences to which we have alluded indiannex the report of Mr. L. E. Fletcher (the Chief Engineer of the Manchester Boiler Association) upon the Preston explosion. This occurrence was attributed to the accumulation of coal gas in the flues, and in order to thoroughly sift the matter, Mr. Fletcher made two visits to the scene of the explosion. On the second visit, Mr. Fletcher was as an analytical chemist is well known to our readers. The result of Dr. Smith's investigations are embodied in Mr. Fletcher's report which runs

This explosion, by which fortunately no one was either killed or seriously injured, occurred to a feed-water heater at a cotton mill, at about seven o'clock on the morning of Friday, October 16. The feed-water water heater at a cotton mill, at about seven o'clock on the morning of Friday, October 16. The feed-water heater or economizer was of the description very generally employed in this locality. It was placed in the main flue between the boilers and the chimney, so as to utilize the waste heat passing off with the gases. It consisted of about 240 vertical castiron pipes arranged in thirty rows of eight each. The length of these pipes was 10ft., their internal diameter 4in., and the thickness of metal three-eighths of an inch. The economizer was fitted with a 3-inch safety valve, while the blowing-off pressure of the boilers to which it was connected was between

601b. and 651b.
This was not the only feed heater on the works. This was not the only feed heater on the works. There were two series of boilers connected to the same chimney, and two economizers, the relative position and arrangement of which will be better understood on reference to the accompanying engraving, in which the exploded economizer is marked A, and the other one B. It is important to observe that the flues for each economizer were not distinct one from the other, but so arranged that both economizers were open to both series of boilers, so that the gases were at liberty to pass entirely that the gases were at liberty to pass entirely through one economizer or entirely through the other, or through both combined. This is a point which must not be overlooked in this investigation.

On the occurrence of the explosion, the economizer

On the occurrence of the explosion, the economizer was torn from its seat and broken into hundreds of pieces, which were scattered to various distances of about 30 ft. or 40 ft. At the same time, the firedoors of all the boilers but No. 6, which was the most distant from the economizer, were violently blown open, and one of the stokers burnt by the flames leaping out upon him, while another man, who was firing No. 4 boiler, started backwards ou finding the flames burst out, but before he had retreated many feet, was blown back on to the coal heap behind him. Besides this, the boiler-house roof was considerably damaged, the side of the engine-house blown down, and the brickwork surengine-house blown down, and the brickwork sur-

rounding the economizer levelled to the ground, while the main flue to the chimney was ripped open, the crown of some of the other flues lifted, one of the boilers moved slightly forward, just sufficiently so to break the steam pipe joint, and the brickwork covering on the top of the boilers marked Nos. 1, 2, 3, 4, 5 loosened, either by shock or other consequence of the explosion, in addition to which many panes of glass in the mill were broken, and a window of one of the upper storeys bulged outward. Altogether, considerable havoc was done, and regarding the amount of masonry dislodged, and the shower of cast-iron pipes and broken fragments that must have fallen, it is surprising that no lives were lost.

With regard to the cause of the disaster, it has been attributed rather to the explosion of coal gas, accumulated in one of the flues, than to the bursting of the economizer from internal pressure. This rounding the economizer levelled to the ground,

of the economizer from internal pressure. This question is one of considerable interest, and on which a good deal of discussion has arisen. Those question is one of considerable interest, and on which a good deal of discussion has arisen. Those who attribute the disaster to the explosion of coalgas, conclude that in consequence of the current through the economizer being checked by the closing of the damper between it and the chimney, an accumulation of gas thrown off from the fires took place within the flue, the gas being either carbonic oxide, or carburetted hydrogen, or possibly a mixture of the two, which, combined with air admitted through the furnace doors, or passed unconsumed through the bars, which is always the case to a great extent, would form a very explosive compound, needing only to be ignited by a red hot spark to cause an explosion. It will be seen on consulting the plan that the furnaces inNo. 4 boiler, which the man previously referred to was in the act of firing at the moment of explosion, and from which he was blown, were situated precisely in line with the chamber of the shattered economizer, so that it is thought that his stirring up the fires kindled the spark which led to the explosion, and thus that the train of argument is complete. Parties engaged in the construction of these economizers say that this view is supported by experience, and that other cases of explosion from the ignition of coal gas have come under their notice, though by no means so violent or destructive as the present one.

On visiting the scene of the catastrophe a few days after the explosion had occurred, when the bewilderment consequent upon it had somewhat died away, and there had been time to correct mistaken impressions and conflicting statements, I gathered that the following were the circumstances

taken impressions and conflicting statements, I gathered that the following were the circumstances

gathered that the following were the circumstances under which the explosion occurred, a consideration of which may be of assistance in determining whether the explosion was one of coal gas or steam. It appears that on the afternoon of Thursday, which was the day preceding the explosion, a leak was found to have sprung in one of the economizers, which prevented the proper water level being maintained in the boilers. As it was not known which which prevented the proper water level being maintained in the boilers. As it was not known which of the economizers was at fault, both of them were shut off, the valves or taps between them and the feed pump, as well as those between them and the boilers, being closed, so that each economizer became completely isolated. Neither of the dampers between the economizer and the chimney were lowered, but the gases allowed to pass through the economizers just as before. In addition to the ordinary dampers, there was a swivel damper between each economizer and the chimney, which was operated upon by the pressure of steam in the boilers, and closed when the steam rose to blowing-off point, so as to prevent unnecessary waste. At the moment of explosion, the steam pressure was very near to blowing-off point, so that as the swivel damper in the flue of the exploded economizer worked more freely than the other, it is not improbable that it the flue of the exploded economizer worked more freely than the other, it is not improbable that it was closed, or nearly so, at the time, and thus that the chamber of the exploded economizer was rendered almost a sealed one, as previously supposed, while the current passed through the other. To prevent an accumulation of internal pressure under the extraordinary circumstances of keeping the economizers bottled up while all the fires were hard at work, the lever of the safety valve on each economizer was raised and blocked up with a bolt, in order that they might be worked on at atmospheric pressure only. The levers of the safety valves were found to be blocked up in this way after the explosion had occurred, while those in charge stated they had seen steam escaping through charge stated they had seen steam escaping through the valves but a short time before the explosion, so that they must have been free.

so that they must have been free.

To put the matter beyond all doubt, however, I thought it best to have the cover of both safety valve boxes removed, and, on doing this, found that the levers and spindles could be lifted without stirring the valves, since they were altogether disconnected, while, although the valve itself on the economizer that had not exploded was perfectly free, that on the other was firmly locked in its soal by a coal of incrustation, and required several smart. by a coat of incrustation, and required several smart blows on its under side from a hammer to liberate it. As there was no connection between the two econo-

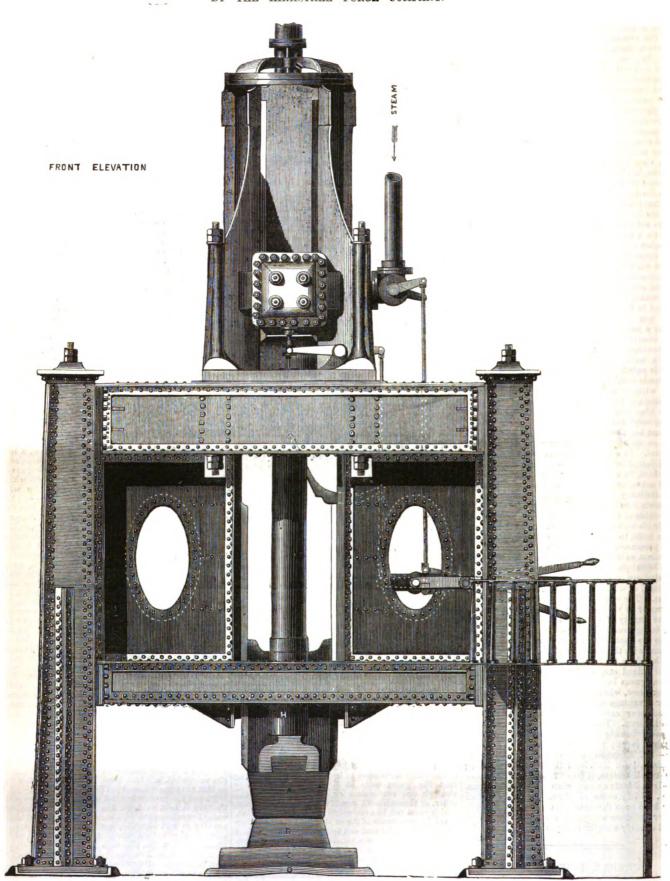

(Continued on page 140.)

<sup>\*</sup> Dr. R. Angus Smith, in experimenting on the gases passing off from several large chimneys, found that much more free oxygen passed of to waste than was consumed in the furnaces.

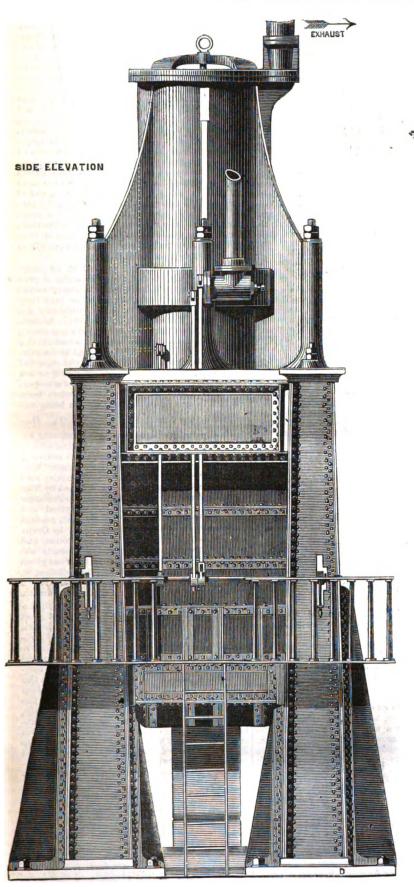

# STEAM HAMMER FOR THE RUSSIAN GOVERNMENT.

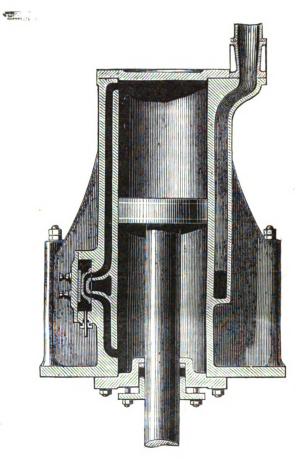

BY THE KIRKSTALL FORGE COMPANY.

# STEAM HAMMER FOR THE RUSSIAN GOVERNMENT.

BY THE KIRKSTALL FORGE COMPANY.

# STEAM HAMMER FOR THE RUSSIAN GOVERNMENT.

THE accompanying engravings represent a 50-ton double-action steam hammer, which has been constructed by the Kirkstall Forge Company, Leeds, to the order of the Russian Government. This hammer, as will be seen, is, with the exception of the cylinder, constructed entirely of wrought iron. The valve gear is so arranged that the hammer can be driven at either side. Steam is admitted to the cylinder by an equilibrium slide valve, a conical valve, as shown in our engraving, being fitted into the upper passage, admitting either the exhaust steam from the under side of the piston, or the full pressure from the boiler to the top side when required, so that the hammer may either fall by its own gravity with the pressure of exhaust from the underside of piston added, or the blow is increased by the admission of full steam from the boilers. The piston and rod are forged in one piece, which, together with the hammer, weigh 15 tons. The cylinder is 46½ in. diameter and 8ft. stroke.

(Continued from page 137.)

mizers, the idea, therefore, that it was impossible mizers, the idea, therefore, that it was impossible for there to be any pressure above the atmosphere within the exploded one, was quite a mistake, and, instead of this, there may have been one of some 5001b or 6001b, from the temperature of the gases in the flue. It should be borne in mind that as the explosion occurred at seven o'clock in the morning, it took place just when there would have been time for the economizer to be thoroughly heated up, so that these circumstances would at once have accounted for the explosion had the rents and flight of the fragments been such as appeared due to internal pressure. Internal pressure, however, will, under ordinary circumstances, burst a cylinder open longitudinally, since the tendency to rend in that direction is precisely double that to rend in the other, whatever may be the diameter of the cylinder or pressure of steam. On examining the fractured pipes, however, none could be discovered that had rent longitudinally, but all that could be seen had rent longitudinally, but all that could be seen had been broken off transversely about midway in their length, as if from an external blow rather than from internal pressure. Added to this, all the fragments were lifted from their original seat, whereas internal pressure, while it would have blown the upper portion into the air, would have tended to drive the lower one into the ground. Thus, the general development of the explosion scarcely appeared to confirm the view that the economizer had burst confirm the view that the economizer had burst from internal pressure, though it is difficult to predicate minutely what the order of results would be in a series of cast-iron pipes in the event of a rupture from some 500lb. or 600lb. internal steam pressure. It is stated, however, that boilers of very similar construction, consisting of a number of castiron pipes, have been severely fired with the safety valve locked down for the purpose of experiment, when it has been found that only one of the pipes has burst, which has let off the pressure, so that no explosion could be produced.

Under these circumstances, I thought it advisable

Under these circumstances, I thought it advisable to consult Dr. R. Angus Smith, F.R.S., F.C.S., &c., on the chemical view of the subject, and to take his opinion upon the possibility of an explosion occurring from coal gas under the special circumstances of the case, and also of its effecting the destruction of property that occurred. With this view I paid a second visit to the scene of the explosion, in company with Dr. Smith. After making an examination of the ruins, Dr. Smith came to the conclusion that both the explosion and its results were possible from the ignition of coal gas accumulated in the flues, but it may be well to give the following extract from a communication received from him on the subject. Dr. Smith says:—"Explosive gases are formed by Dr. Smith says:—" Explosive gases are formed by simply mixing gases and vapo rs from coal with air. simply mixing cases and vapor is from coas with as Indeed, every fire is making gases which explode when heated with air, so that the question arises why are we not blown up daily? The answer is because the currents of air are so constant, penetrating, and intrusive that they follow the gases, and trating, and intrusive that they follow the gases, and thus a constant and steady fire is the consequence, instead of a hasty and violent one. Every furnace, however, especially if a large one, becomes to some extent a gas retort, and generates exactly the same products, though burning them more or less. Stop the draught and gas is made. Let air enter and an explosive mixture is formed at once. Thus there is no difficulty in accounting for the given. there is no difficulty in accounting for the circumstances under examination by an explosion of gas. The long furnaces, with the impeded drught and hot The long turnaces, with the impeace aright and not flue, were capable of forming gases abundantly powerful to produce all the effects developed by the explosion under consideration. In support of this I may mention that, a short time since, I happened to enter works a day or two after the occurrence of two explosions, which could be accounted for in no other way than that just mentioned. The wonder rather is that such explosions occur so seldom."

Notwithstanding that it may be quite possible that the explosion arose from the ignition of coal gas, it scarcely appears to admit of demonstration that it actually took place from this cause. If it did, it may be asked, why had not the catastrophe occurred long before, as the swivel dampers had been at work for months, constantly opening and closing as the steam rose and fell, and there was nothing unusual in the condition of the flues excepting that unusual in the condition of the flues excepting that they were flooded with about a foot of water, which had escaped from the economizer? Besides this, the fact that the safety valve was free in the economizer that did not explode and locked fast in the one that did, while the explosion occurred at seven o'clock in the morning, just an hour after starting, when the economizer would have had time to be well heated up, and an internal pressure accumulated, are strong arguments in favour of the explosion are strong arguments in favour of the explosion being due to steam pressure. Thus there appears to be considerable probability in favour of both views. though scarcely sufficient evidence to decide posi-tively on either one, and to justify a decided opinion

as to whether the explosion arose from coal gas or

internal steam pressure.

The object of these inquiries, however, is to show how to avoid similar disasters in future, and it is thought that this end will be attained by pointing out such precautions to be adopted in the construcout such presentions to be supplied in the construc-tion and management of these economizers as will guard against their explosion either by coal gas on the one hand, or by steam pressure on the other; and with this view the two following recommenda-

and with this view the two following recommenda-tions are given:—
To prevent the explosion of economizers from internal pressure, they should be fitted with a thoroughly reliable safety valve, not liable to de-rangement by incrustation. No valves would be more suitable than those of external dead weight pendulous construction, which are made without levers, fangs, or spindles to jam fast, and instead of being boxed in out of sight, are entirely open to view. Valves of this description are in very general use on steam boilers, and hundreds of them, under use on steam boilers, and hundreds of them, under the inspection of this Association, have been satis-

the inspection of this Association, have been satisfactorily at work for years, so that their adoption may be confidently recommended.

To prevent explosions from coal gas, there should be no chambers in which the gas can lurk. The arrangement in the present instance was eminently peculiar, and most conveniently contrived for courting an accumulation of gas, so that it would be advisable to convert the two economizers into one, and have but one absorber instead of two. and have but one chamber instead of two. In some instances the ordinary reserve flue might become a source of danger if closed by a damper near to the chimney, but this would be area. damper at its entrance, so that there may be no void chamber in which the gases may accumulate. For the same reason, when the reserve flue is in use, the economizer should be cut off by a damper at the

entrance, and not at the chimney.

This will be more readily understood on a consul tation of the accompanying engraving, in which the reserve flue is shown in full work, and the economizer stopped off, with the damper between it and the Chimney closed, and the one at the entrance opened. Under these circumstances there will be little or no current through the chamber, and thus an accumula-tion of gas might settle in it and become ignited by sparks from boilers Nos. 2 and 3, which are directly sparks from boilers Nos. 2 and 3, which are directly opposite to it, very much as in the case of the explosion just reported above. It will be seen that the danger of this would be averted by closing the damper at the entrance to the chamber of the economizer, and also that the damper in the reserve flue is in a much better position close to the boilers than at the chimney. It will be well for those using econo-mizers to overhaul their arrangements and see that they do not admit of such combinations as those illustrated in this plan, and, if necessary, to have their dampers altered accordingly. If these simple precautions are adopted, it is thought that well-made feed water heaters or economizers can be worked on in safety, and that the confidence so long reposed in them may be restored.

L. E. FLETCHER Chief Engineer.

EXPLOSIVE COMPOUNDS FOR ENGINEER ING PURPOSES.

> BY MR. PERRY F. NURSEY. (Continued from page 122.)

second of the two principal opponents which gunpowder has to contend with is guncotton. This proposed substitute was discovered by Schönbein in 1846, since which time it has been greatly improved as far as regards manufacture. and attempts have been made in various countries to apply the material to purposes for which gunpowder hitherto had been alone used. In England its manufacture on a large scale was commenced by Messrs. Hall, the gunpowder makers, at Faversham. An explosion, however, soon occurred at the works, killing a number of men, the cause being the spontaneous ignition of gun-cotton. This led to the abandonment of the manufacture on a large scale, and gun-cotton was apparently lost sight of until 1854, when Hadow published some results of his investigations into the nature of gun-cotton. In France, gun-cotton was made the subject of experiment as early as 1846, and its manufacture was carried on at the Government Powder Works at Bouchet, near Paris. Here, however, disastrous explosions also occurred-one in March, 1847, and two in 1848, several lives being lost. These disasters appear to have put an end until quite recently to experiments with guncotton in France. In Austria, where great attontion has been paid to gun-cotton, Baron Von Lenk was commissioned to inquire into the merits of the material, and a manufactory of gun-cotton was established at the Castle of Hirtenburg, near Vienna. The material was applied for a while to cannon, but soon grew into disfavour, owing to its

occurred in a magazine at Simmoring, Vienna, which caused the use of gun-cotton in artillery to be put a stop to; and in December, 1866, by order of the emperor, the use of guncotton by the Austrian artillery and corps of exgineers was entirely prohibited.

Important progress has, however, been made in the development and practical application of guncotton by Professor Abel and others since its study was resumed in this country about six years ago. Very considerable quantities of the material have been manufactured at the works of Messrs. Prentice, at Stowmarket, and at the Government Gun-powder Works at Waltham Abbey; its employment as a blasting agent is steadily increasing in several important English mining districts; and some success has attended the employment of guncotton cartridges for sporting purposes. system of manufacture of gun-cotton, as perfected by Baron von Lenk, has undergone but trilling modifications in its employment in this country. It has been made the subject of careful investiga-tion by Professor Abel, and the results furnished by many experimental manufacturing operations, and an examination of the products, have shown that the process of converting cotton into the most explosive form of pyroxilin or gun-cotton, and of purifying the material, have been so greatly perfected by Baron von Lenk as to render a strict adherence to his simple and precise instructions alone necessary to ensure the preparation of very uniform products, which are much more pure than those obtained in earlier days.

Although the conclusions arrived at by many chemists who investigated the composition of guncotton, soon after Schonbein's discovery, varied very considerably, the constitution has been very generally regarded as definitely established by the researches of Hadow, published in 1854. According to that chemist, the most explosive gun-cotton has the composition expressed by the formula C . H<sub>7</sub> N<sub>3</sub> O<sub>11</sub> (which was first assigned to the substance by W. Crum, in 1847), and may be regarded as cellulose, in which three atoms of hydrogen are replaced by three molecules of peroxide of nitrogen.
The name Tri-nitro-cellulose has therefore been assigned to gun-cotton, its constitution being expressed by the formula C a  $\left\{\begin{array}{cc} H & 7 \\ 3 & N & O \end{array}\right\}$  O s. Hadow's conclusions have since been confirmed by other chemists, more especially by Redtenbacher, Schrötter, and Schneider, who have analyzed specimens of gun-cotton prepared under Von Lenk's directions. An experimental inquiry into the composition of gun-cotton, as obtained by Von Lenk's process, has been instituted by Professor Abel; and the very numerous analytical and synthetical results which he has obtained, confirm the correctness of the formula assigned by Crum and Hadow to the most explosive gun-cotton, and demonstrate satisfactorily that the products obtained by following strictly the instructions given by Von Lenk, are invariably tri-nitro-cellulose, in a condition as nearly approaching purity as a manufacturing operation can be expected to furnish.

Professor Abel has identified himself with the advancement of the gnn-cotton question, and great credit is due to him for the light he has thrown upon that question by long and patient experimental research. Still greater credit is due to him for having discovered and perfected a method of treating gun-cotton whereby it is rendered nonexplosive when burnt in the air, but in which the full energy is developed when fired in a close chamber. The method consists in reducing the gun-cotton fibre to a fine state of division or pulp, as in the process of paper making, and in convert-ing this pulp into solid masses of any suitable form or density under a pressure of 18 tons to the square inch. This method of manufacture is now carried out by Messrs. Prentice at their works at Stowmarket. To the pulping mainly is due the safety attained, as it ensures uniformity in washing, whereby the cotton is thoroughly freed from all acid, and thus every chance of spontaneous com-bustion is removed. The compression causes combustion to proceed slowly in the open air, owing to the condensed condition of the fibres, which, in the lose state of cotton or rope, burn very rapidly. The gun-cotton is made into small cylindrical charges, which are both portable and convenient for use. The principle of thus combining safety with force in a highly condensed form has produced very valuable results. A series of severe trials, extending over a considerable period, have proved gun-cotton, in its present improved form, to possess all the attributes which should be found in a material for blasting purposes. uncertainty of action. In 1862 an explosion These trials were carried out by Mr. Prontice with

<sup>\*</sup> From these remarks of Dr. Smith it would appear that there is danger from irregular and intermittent currents in furnace flues, since where they exist gas may be liberated at one time and air mixed with it at another, and thus an explosive mixture formed, so that the effect of the intermittent action of lively swived dampers upon leases but fless is a noint worthy of investigation. large hot fires is a point worthy of investigation

the view of satisfying railway companies of the absolute safety of the material. Mr. J. Wilson, the absolute safety of the material Mr. J. Wilson, the goods manager of the North-Eastern Railway, directed these experiments, and made a report thereon, from which document the author obtains

the following particulars:—
First, a small box containing 125 charges of the gun-cotton, and said to be equal in effect as a blasting agent to a quarter cask of gunpowder, When the flame reached was ignited by a fuse. the gun-cotton, there was a great blaze like the burning of a heap of loose straw, but no explosion. In less than half a minute there was no flame, except from the burning of the brown paper in which the gun-cotton had been packed inside the box. The box was of wood about \(\frac{1}{2}\)in. thick, and was nailed, but not bound with iron at the corners; it was one of the ordinary packages used for sending the cotton out. After this, a number of charges were laid on the rails near the coal depôts, and coal waggons were run over them, when some of them were ignited, others were not. Some charges were then placed so that an engine should pass over them, and they were all ignited. Mr. Prentice took an axe and chopped one charge into several pieces; there was no explosion or ignition. Small pieces of gun-cotton placed on the iron rim of a wheel and sharply struck with a hammer, exploded, or, rather, detonated. In all the cases where ignition was produced by concussion, whether of a hammer on iron, or of the wheels of an engine or waggon on the rails, it was very evident that only so much as was actually struck exploded or detonated, the part not struck firing from the explosion, and burning like straw or flax. In order to make sure that he was really dealing with the article which produces such an effect when exploded in close confinement, Mr. Wilsonhad a hole bored in a large block of hard tough wood, in which he placed a charge of gun-cotton with a fuse attached to it. He then filled up the hole with broken slate tightly rammed, and fired the fuse. When the gun-cotton exploded, the block of wood was shivered to pieces, and the fragments were blown several yards away. The result of these experiments convinced Mr. Wilson that railway companies might safely carry guncotton along with other goods in ordinary waggons, adopting the same rules as apply to the conveyance of cartridges. The North-Eastern Company acting on Mr. Wilson's recommendation, now carry The North-Eastern Company, the gun-cotton as ordinary goods in covered

waggons.

Whilst upon the question of gun-cotton transport, it may be interesting to notice a report of Colonel Boxer upon the comparative risks of guncotton and gunpowder in conveyance. The colonel is of opinion that no greater risk of an explosion cotton charges by railway or other modes of conveyance than is incurred by the transport of ordinary gunpowder. ordinary gunpowder. He further states that in the event of an accidental explosion of these charges, the amount of damage to life and property would not be greater than that which would result from the explosion of the same bulk of ordinary gunpowder. Finally, he thinks that the mode of packing the charges in deal boxes is preferable to that of packing in strong iron cylinders. The expressions with reference to the comparative in accidental explosion are, of guarded; but the author feels assured, from comparative trials made by himself on a small scale, that the damage would be much less with cotton than with powder. He has found the compressed gun-cotton perfectly inexplosive so long as the atmosphere has access to it.

The most recent feature in the development of the gun-cotton question is the rendering of the safety gun-cotton, just referred to, violently explosive when in the open air. This is effected by means of a detonating tube attached to a fuse, similarly to the method adopted by Mr. Nobel to explode dynamite. This safety gun-cotton, there-fore, which will only burn in the open air if ignited by any ordinary means, will, it appears, develope all its deadly energy if fired under the same unconfined conditions, but with a special detonating fuse. In proof of this, some experiments were recently carried out at Stowmarket by Messrs. Prentice. The author appends a few particulars of these trials, which he correct, although he was not present at the time. The first experiment consisted in placing a disc of gun-cotton, weighing about 11b. 1oz., on the stump of a tree lately felled, and igniting it by an ordinary piece of miner's fuse. At the instant of ignition it was enveloped in flame, and moved about for the two or three seconds required for its combustion. About half the quantity was then

placed on the same spot, and ignited by a small detonating fuse. A sharp, sudden report was heard, and the stump was found on inspection to be partly penetrated just where the charge had lain, while the twigs of the hedge close by suffered severely. The root of a large tree which lay on the ground was then attacked. A disc of gun-cotton, weighing about 1lb. loz., was placed in a hollow beneath it, a detonating fuse being inserted. The explosion shattered the old stump, and scattered its fragments in all directions. The next experiment was calculated to prove the question from a military point of view. A row of palisades, composed of trunks of trees, some 18in. in diameter, and all sunk 4ft. into the ground, was provided. A long tree trunk lay touching the foot of the palisade, and upon this 51b. of guncotton was laid. Wires communicating with a magnetic apparatus were affixed to a detonating tube, which was placed in contact with one of the discs of gun-cotton. Upon the explosion only one trunk was seen to fly away from the spot, and that proved to be the one upon which the charge had been placed; the palisades, although shaken, were comparatively unharmed. A charge of 15lb. of gun-cotton was then placed against another part of the stockade, which was perfectly sound, and fired. The result was a general smash up, and a tumble over of all the trunks in numerous pieces; and so it ought to have been, with such a charge as was employed.

Having brought the history of modern explosive compounds down to the very latest period—for the series of experiments last described only took place on the 22nd of last month—it will be as well, in conclusion, briefly to glance at their comparative merits. Bearing in mind the rule laid down in the opening part of the paper, that a per-fect blasting material must be safe to handle and powerful in use, we may dismiss from our minds all those substitutes for gunpowder in which the dangerous chlorates and nitrates occur. author cannot even make Reveley's white gunpowder an exception, although Mr. Reveley has long made and used it himself with safety. But this is a very different thing to the manufacture, transport, and use by rough hands of hundreds of tons a year. Neumeyer's safety powder appears to embody all that is required as regards safety and strength, although its power falls far short of that possessed by either dynamite or gun-cotton. But as this powder has not been commercially introduced into England, and, in fact, is hardly known beyond the scientific world, it cannot be quoted as a material of which engineers can make choice for blasting purposes. Next in order, we have nitro-glycerine in its improved condition of dynamite. It is between this substance and compressed gun-cotton that the contest appears to lie, and they are both such excellent materials that the probability is they will both succeed in superblasting operations. Dynaseding gunpowder in mite has superior difficulties to surmount than those which have attended the development of gun-cotton. The dangerous character of nitroglycerine has so impressed itself upon the public mind, that it will require time to remove those impressions, and to establish confidence in the safe material-dynamite. If we compare the relative safety of dynamite and gun-cotton, there appears to be no difference between them. The only doubt upon the author's mind is whether, after long storage, any dangerous change may take place in either of the two substances. Mr. Nobel has endeavoured to answer this question with regard to dynamite, but the author thinks a year is scarcely sufficient time to determine this matter in such a comparatively recent discovery. So, too, with regard to the compressed gun-cotton. The author thinks a longor time must elapse before the new form of gun-cotton can be pro-nounced absolutely safe. The old gun-cotton was supposed to be safe in storage, but accidents at home and abroad have shown the contrary; and, however Professor Abel may now have eliminated the element of danger, as far as chemistry can, it is not for any one to say it is a reliable material until such time-tests have been applied as shall satisfy not only chemical science, but common sense. It is to practical common sense that all these matters ultimately address themselves, and it would be of no avail, commercially, if all the leading chemists in Europe were to pronounce a substance safe if they could not support their opinions by experiments which the public could understand, and in which, therefore, they would place faith. With regard to the question of the

It would appear, however, to the author that dynamite was actually the stronger of the two, for, from his experience of that thinks that much less than 5lb. of dynamite would have effected what 5lb. of gun-cotton failed to do at the palisade experiments—viz., to demolish it. But this is a question that can best be settled by comparative experiments, which the author suggests should be carried out with that view.

It, therefore, results that dynamite and compressed gun-cotton equally fulfil the conditions required of a safe and efficient blasting material as far as science at present can determine, whilst dynamite appears to possess the superior shattering power. It should also be borne in mind that a bore hole will take up nearly double as much dynamite as compressed gun-cotton, as the dynamite is like moist sand, and can be packed into the irregularities of the hole, whilst gun-cotton is in cylindrical pellets, which can only occupy their own diameter in the hole. Hence, if dynamite was even inferior in point of power, weight for weight, in its application to blasting, it would be preferable. The author does not agree with the theory that the power of gun-cotton is increased by firing it with a percussion fuse. He can only conceive the fuse to act upon the gun-cotton in the way that a whip does upon a horse; it accelerates its action, but does not increase its strength. He thinks that the same explosive power would be developed in compressed gun-cotton when fired by an ordinary fuse in a confined space, as when fired by a percussion fuse under the same conditions, although it has been demonstrated that the percussion fuse will develope the energy of the guncotton in the open air, under which condition the ordinary fuse will certainly not explode, but will only ignite it.

Such, then, is the present practical position of explosive compounds with regard to engineering The most deadly explosives are at hand ready for work, but as harmless for mischief as so much sawdust or paper. They may be transported with safety, and played with by a child when unconfined; but when imprisoned they will tear down the hardest rock in liberating their These are some of the marvels of the age in which we live, but which some new scientific discovery may eclipse before many years pass over.

## THE NEW LIMEKILN AT INGLETON.

IN the spring of last year, Messrs. Clark, Wilson, and Co., began to build an extensive limekiln on the principle of a German patent. As the works have been completed under the management of Mr. Bagnall, C.E., and just been brought into working order, a description of the kiln is not without interest. The scene of operation, says the "Leeds Mercury," is one of unusual activity for this quiet Mercury," is one of unusual activity for this quiet neighbourhood. The kiln, which is built on a flat on the north side of a clear mountain stream, with millions of tons of limestone rock on its back, pre-sents at a distance, and especially from the railway sents at a distance, and especially from the railway bridge, a unique appearance. The kiln is oval, and measures in circumference 450ft., being surrounded by a road for the use of carts. At the height of 4ft. from this road, there is a platform all round the kiln, 64ft. wide. From the platform there are fourteen arched openings into the chambers, for the purpose of taking in the stone and bringing out the lime. Each chamber, which is 9ft. in height at the centre of the arch and 18ft. wide on the floor, is capable of holding 100 tons of limestone, and as the stone is calculated to lose by burning two-fifths of its weight in carbonic acid and moisture, a chamber yields at one draw about 60 tons of lime. As it requires many days to convert the stone into lime, and three days to cool a chamber before it can be requires many days to convert the stone into lime, and three days to cool a chamber before it can be discharged, 60 tons of lime is the amount produced per day. From the platform to the feeding chamber it is in perpendicular height 11ft., but, as the wall slopes, it measures 14ft. The feeding chamber extends over the whole of the fourteen lime chambers, and is 150ft. in length and 65ft in breadther which measures from the floor to the This chamber, which measures from the floor to the This chamber, which measures from the floor to the ridge 14ft., is covered over with a wooden roof, which cost £200. In this chamber, into which there are forty-one brick openings 6fft high by 5ft. wide, there are 424 feeding holes, through which, by the use of a small funnel and scoop, the fires are supplied with fuel. In the centre of this chamber are fourteen valves 2ft. 1in. in diameter, connected with the chambers which surround a central chamber in the kiln, called the smoke or carbonic acid chamber, through which the carbonic acid gas and moisture pass through a long flue and escape from a brick chimney erected on the top of Meal Bank. As all the smoke is consumed, and the men who feed the fires are under cover, and have only to use a wheelplace faith. With regard to the question of the relative powers of dynamite and gun-cotton, these appear also to be nearly evenly balanced; we may take it that for all practical purposes they are so. 500,000 building and firebricks, which cost about

£1,000, have been used in the erection of the kiln. The kiln, the licence of the patentee, and necessary material for carrying on the works, have cost about

ROLLS COURT, CHANCERY LANE, FEB. 16. Before the MASTER OF THE ROLLS.

CROSSLEY V. DIXON.

The arguments were resumed in this case, which involves the question whether certain portions of the mechanism of some Jacquard looms of an improved construction supplied by Messrs. Sharp, Stewart, and Co., to the defendants, and used by them in the manufacture of Brussels and velvet pile carpets, are infringements of the plaintiff's patent rights.

Mr. Grove, Q.C., Sir Richard Baggally, Q.C., and Mr. Cracknall appeared for the plaintiffs; Sir Roundell Palmer, Q.C., Mr. Jessel, Q.C., Mr. Speed, and Mr. Aston appeared for the defendants.

At the conclusion of the speech of Mr. Grove, Q.C., in reply,

His lordship, addressing him, said, in the event of his coming to a conclusion that the case was not governed by the decision of the House of Lords in the former suit of "Crossley v. Dixon," in 1863, he should most probably direct issues to be tried before a jury with reference to the questions of infringement; or, if the parties were willing, he would decide the question himself, in which case he should desire the attendance of one of the gentlemen on either side who had given evidence in the cause, with the models and portions of mechanism which had been produced in court during the hearing.

SMITH'S LIQUID FUEL FURNACE. TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Referring to your notice, under the above heading, in last week's MECHANICS' MAGAZINE, I beg leave to point out that the injecting into furnaces of liquid fuel, in the form of spray, by means of superheated steam, so that it impinges against fireclay slabs or similar material, is well known as Messrs. Wise, Field, and Aydon's system, and is covered by Letters Patent granted to them in 1865. You may, perhaps, remember having witnessed one of the many successful applications of their apparatus at Lambeth more than two years ago, of which a report appeared in the Mechanics' Magazine of February 8, 1867, where a description of the arrangements is given. As the apparatus described in your last number is similar to Messrs. Wise, Field, and Aydon's, I trust that you will insert this letter in justice to the owners of their patent.—I am, Sir, yours, &c.,

Chandos Chambers, Buckingham, street Addalabi

W. LLOYD WISE Chandos Chambers, Buckingham-street, Adelphi, London, February 18, 1869. [As Mr. Smith's is a patented invention, and his

system has been in successful operation for a year or more, why have not Messrs. Wise, Field, and Aydon applied for an injunction against the alleged infringement of their invention?—ED. M. M.]

## TO CORRESPONDENTS

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 is. 8d. yearly, or 10s. 10d. half-yearly, payable in

oi £1 18. 8d. yearly, or 10s. 10d. half-yearly, payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Lotters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith, Ed. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 61. per line, or 5d. per line for 18 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type, Special arrangements made for large advertisements.

JOHN BROWN, Peniston-road, Sheffield will find.

as type; Special arrangements inside for large agrerisements.

JOHN BROWN, Peniston-road, Sheffield, will find in M. Reimann's work on aniline and its derivatives, the information he requires respecting aniline colours. It is published by Messrs. Longmans, Paternoster-row, London.

L. W. B.—If you will send your name and address we can put you in the way of obtaining the information you require. We do not attend to letters which are not authenticated by the writer's name and address. We do not require these for publication, but as a proof of the writer's good faith. Many communications go direct to our waste basket owing to this omission.

H. A. K., whose letter we received last week, will also notice the above remarks. If, however, he requires the information asked, he will doubtless obtain it by applying at the City Chamberlain's Office, Guildhall.

G. D., Manchester.—Gun cotton has been so modified by Messrs. Prentice, under Professor Abel's system, that it can be, and is, used for sporting purposes inclosed in a cartridge case.

THE winter general meeting of the National Rifle Association will be held at Willis's Rooms on Thursday, the 4th of March, at 2.30 p.m.. Field-Marshal his Royal Highness the Duke of Cambridge K.G., in the chair.

An Admiralty order received at Chatham Dock-yard directs the discontinuance of a number of intricate and useless returns. The result will be that a vast amount of unprofitable labour on the part of the clerks will be entirely got rid of.

WE hear that the full force of Colt's Armoury at Hartford, Connecticut, is now engaged on the con-tract to furnish the Russian Government with 80,000 Berdan rifles, and upon the 100 Gatting guns ordered. The armoury is to be enlarged.

THE Lords of the Admiralty have decided on the retention of the ropemaking establishment at Chatham Dockyard, which, on the abolition of the ropery department at Portsmouth and the other dockyards, will be the principal establishment for the manufacture of rope for the whole of the Navy.

A LETTER from Warsaw states that great con-sternation prevails in that city in consequence of a decision of the Russian Government to enlarge the fortifications. More than a hundred houses are to be expropriated, and the indemnities offered to the proprietors do not amount to two-thirds of the

The trial trip of the great Prussian iron-clad the "Konig Wilhelm," which was to have been made for speed down the river last Saturday morning, was unavoidably postponed until the next spring tides, owing to the boisterous state of the weather at the river's mouth, and a condition of wind and tide that would have material effect upon a trial made for most only. speed only.

THE silver medal of the Royal Humane Society which was voted to Lord Bury for his very courageous rescue of life at Christchurch, Hants, on the 6th October last, has been sent by H.R.H. the Commander-in-Chief to the Inspector General of Reserve Forces for presentation to Lord Bury in recognition of his galantry. Lord Bury is Colonel of the Civil Service Volunteers.

An important experiment was carried out at Shoe buryness on Thursday w.ek to test the safety of loaded shells for rilled guns and the effects produced when some are struck within a casemute by an enemy's missiles. The results were very satisfactory in showing that shells not actually hit would not be fired by a contiguous explosion of others.

ADMIRAL Sir Houston Stewart, G.C.B., has been appointed Governor and Visitor of Greenwich Hosappointed Governor and visitor of Greenwich Hos-pital at a salary of £1200 per annum. Sir Houston will have to vacate his good s.rvice pension, which will be placed at the disposal of Mr. Childers; but he will not have to leave the active list, and will, as a matter of course, rise in due order to be an Admiral of the Fleet. But, on attaining this exalted rank, his connexion with Greenwich will naturally cease.

THE last Friday evening lecture at the Royal Institution was given by Colonel Jervois, R.E., "On the Coast Defences of Great Britain." The gist of his authoritative remarks may be briefly thus put. minutes.

The armyand navy are the vital principles of defence the fortified arsenals and harbours are the centres of refuge and action for both. Take away the fortificaretuge and action for both. Take away the fortinea-tions, and the auxiliary forces cannot be turned to account; whilst the army will be utterly insufficient for the duties thrown upon it, and the navy will be scattered unsupported; and with no protected home.

THE first batch of 61 rifled guns, converted on the Palliser principle from smooth bore cast-iron guns, has been received at Woolwich. The guns have all been proved by the Royal Gun Factories, and 60 have been passed into the service, one gun being rejected for defective manufacture. A second batch of 30 guns is on the road from the Elswick Ordnance Works, Newcastle-on-Tyne. It is stated that Go-vernment have decided to convert a considerable number of cast-iron guns next year in the gun factories at Woolwich.

factories at Woolwich.

The trials of the old 68-pounder cast-iron gun, condemned as unserviceable from fissures in the vent after firing about 400 rounds in its smooth-bore state, and converted into a 150-pounder rifle gun upon Mr. Parson's principle, were reported by us. At the same time, an explanation was given of the severe test to which it had been put at Shoeburyness with satisfactory results, and the further endurance test it had to undergo at Woolwich. In the course of these tests a crack was observable, and the firing was discontinued by order. The gun has since been examined, and the tube has been ascertained to be perfectly sound, as the inventor predicted it would be.

examined, and the two has been ascertained to be perfectly sound, as the inventor predicted it would be. ACCORDING to the "Statistique Médicale de l'Armee Française pendant l'Annee 1866," contagious disease infected 97 per 1,000 of the effective strength disease infected 97 per 1.000 of the effective strength in that year, being an average loss of each patient's services for thirty days; the total loss being equivalent to the s rvices of the whole French army for nearly three days. All French garrison stations are under sanitary restrictions, and the beneficial effect of this restriction is well shown when the health of the French army is compared with that of the British the French army is compared with that of the British army. The number of men affected in the portion of the British army at home was, in 1866, 258-5 per 1,000 of mean effective strength, or nearly two and a-half times greater than in the French army. The average loss of each patient's services being about twenty-three days, and the total loss equivalent to the services of the whole army for almost six days.

# Miscellanea.

On Tuesday last the excavation of the shaft for the subway from the Tower to Southwark was commenced on the property of the Crown at Tower-

ELEVEN champion ploughing matches have already ELEVEN champion ploughing matches have already taken place this year in different parts of the kingdom, but the principal plough manufacturers have not sent their own men to compete for the prizes, but have left the success of their ploughs to the local ploughmen. Six of these matches have been won by men with Messrs. Ransome's ploughs, one has fallen to Messrs. Howard's, and the remainder to other makers. remainder to other makers.

AT a meeting of the Fellows of the Royal At a meeting of the Fellows of the Royal Botanic Society, held on Saturday last, Mr. Charles Robert Turner in the chair, the names of the following candidates for the fellowship were read:—Sir Charles Wheatstone, Mrs. Sowton, Baron de Teissier, Mrs. Weston, Mr. Charles J. Kino, Mr. James Purdey, Mr. Robert Alger Newbon, Mr. John Miles and Mrs. Merton, in addition to several elected on the same day.

At the ordinary meeting of the Society of Engineers, held on Monday, the 15th inst., Mr. F. W. Bryant, President, in the chair, a paper was read on "The Drainage and Water Supply to the Town of Fareham," by Mr. Thomas Buckham. The following candidates for election as members were announced—viz., Messrs. John Blackbourne, resident engineer, Limehouse Basin Improvement Works; and John Baldwin, engineer, Navarino-road, Dalston. road, Dalston.

On Monday morning the tide in the river Thames rose to an unusual height, inundating the wharves and warehouses adjacent to both banks, and causing considerable damage to property. In the low-lying districts at Lambeth, Vauxhall, Nine Elms, and Battersea, the water ran along the streets at an alarming pace, flooding the houses, and necessarily damaging property to a serious extent. At the upper part of the river the stream was swollen, and immense tracts of land lay under water, especially in the neighbourhood of Reading, Cookham, Maiden head, Windsor, and Datchet. head, Windsor, and Datchet.

WB read in the "Derby Mercury," in a report of a meeting of the Heanor Local Board, that "Mr. Beardsley, in a speech of some length, proposed the appointment of a qualified surveyor at a minimum salary of £20 per annum. It appeared that the person who at present filled the office of surveyor, when not employed as such was working above. when not employed as such was working along with labourers paid by the board, and Mr. Beardsley con-sidered that it would be much better to have the sidered that it would be much better to have the office of surveyor by itself. The proposition was not seconded, and so fell to the ground. The Board, however, agreed with Mr. Beardsley's views, excepting that they did not see their way to getting a sufficiently qualified person to undertake the office of surveyor at the salary in question." We should think not! think not!

think not!

At the end of 1867 the number of towns in Italy lighted by gas was 86. The annual production of gas amounted to 30,189,941 cubic metres (upwards of 1,066,016,916 cubic feet). The quantity of coke produced was 67,668 tons, and 6,968 tons of tar. The total value of these products amounted to 14,188,598 francs. Upwards of 1,177 workmen are employed in this industry, and their wages amount annually to 885,925 francs. The price of gas in the north of Italy varies in different towns from 40 to 50 centimes per cubic metre (equal to from 9s. 1d. to 11s. 4d. per thousand cubic feet). At Milan the price of gas is 45 centimes per cubic metre (10s. 2;d. per thousand.) The public lighting is, however, paid by the town at 28 centimes per cubic metre (6s. 4½d. per thousand), so that a street lamp consuming 120 litres per hour costs 0.0336 of a franc per hour. costs 0.0336 of a franc per hour.

AT a special general meeting of the members of the Newspaper Press Fund, held on Saturday last, at the offices, 24, Cecil Street, Strand; Lord Houghton the president, in the chair; the supplementary report and balance sheet for the six months ending Dec. 31st, 1868, showed that the invested capital of the 31st, 1868, showed that the invested capital of the society now stands at the sum of £4422 11s. 7d. consisting of £3122 11s. 7d. New Three per cents.; £700 Great Indian Peninsular Railway Debentures; and £600 Eastern Bengal Railway stock, guaranteed by the Imperial government. The grants made by way of relief during the past half-year amount to £165, or for the whole year just elapsed, to £305. The amounts so granted ranged from £10 to £50, and the cases relieved were 15 in number, all of them being of such a character as clearly to indicate the

2345 A. C. M. PRINCE, Trafalgar-square. Bell-pul. (A communication). Dated July 25, 1868.

The object of this is to facilitate the pull against the action of the bell spring, by converting the ordinary horizontal action of the handle into a downward lever action. This is effected by forming a slot at or near one end of the plate to which the bell-pull is applied, such plate being screwed to the door jamb; at the opposite end of the plate another slot is formed, across which a pintle or shaft is arranged, which consists of a wire or rold so placed in a mould as to be cast into and fastened to the sides of the slot. The handle consists of a bar or plate, to the outer side of which is secured an arm, terminating in a suitable knob or button, which may be of any ornamental form, and is attached to the end of the bar. To the inner side of the bar is secured a tongue, consisting of two parts, joined or hinged together. One end is firmly connected to the bar, and is slightly curved in a downward direction. The other part is also curved; the other end of this compound tongue terminates in a hook or eye, to which the bell wire is attached.—Patent abandoned.

2347 A. M. Clark, Chancery-lane. Steering ressels.

amounts so granted ranged from £10 to £50, and the cases relieved were 15 in number, all of them being of such a character as clearly to indicate the value of the benefits derivable under the fund. The roll book of the society comprises 247 members, of whom 170 are resident in London, and 77 in the country. The number of life members is 61.

The meeting of the Royal Horticultural Society, held on Tuesday last, was a most successful one there was a perfect blaze of flowers, among which the cyclamens and various forms of Chinese primproses were greatly admired. The collection of apples was most remarkable, not only for the numerous varieties which were exhibited, but for the wonderful state of preservation, considering the season. Mr. Wilson Saunders, F.R.S., presided, and the following candidates were elected fellows, viz.:—Lord Abinger, Samuel Asser, Francis H. Bacon, Edward George Barr, Mrs. Somerville Burney, Thomas Chapman, Major General J. W. Croggan,

the bows, and have two lateral branches, with a cock placed at the junction of the pipes, by placing one or other of the branch pipes in communication with the longitudinal pipes, a power is obtained at each end of the vessel for overcoming its inertia and moving it to the right or left.—Patent completed.

2348 A. J. Thorman, Lime-street. Molive power. (A communication). Dated July 27, 1868.

For this purpose a tank is employed, at the bottom of which are fastened two upright pieces, at such an angle from each side of the box as may be necessary; between these two pieces two wedge or trapezium pieces are placed. These are made so as to move to and fro against the sides of the upright pieces; another wedge or is-secles triangle-shaped piece is used which fills up the space; this is also made to move to and fro, and these three pleces are constructed so that as they may move forward or in one direction they are airtight or watertight at the sides in contact with one another, and also on the sides, in contact with the upright pieces; but having reached the distance that they have to move, two small plates or valves shift or open, which cause the contact between the wedge pieces to be broken, and allows them to return freely when the two small plates or valves again occupy their places or are shut. Adjoining, is another wedge-shaped or right-angled triangular piece, which is also made to move to and fro, having at the same time a movement from side to side. This piece has a stud or pin which works in a groove of a slide-piece, and this slide-piece is driven, it will give the former a side to side motion as well as to and fro, causing the resistance to be materially diminished.—Patent sbandoned.

2349 J. A. Hoog. Edinburgh. Lamp. Dated July 27, 1868. This lamp is constructed as follows:—Two tubes are

materially diminished.—Patent abandoned.

2349 J. A. Hogo, Edinburgh. Lamp. Dated July 27, 1868. This lamp is constructed as follows:—Two tubes are employed on the Bunsen lamp principle, one of which is of smaller diameter than the other; the smaller tube is of smaller diameter than the other; the smaller tube is of placed within the larger tube; one of the tubes is placed in communication with condensed gas or air, or a mixture of both. The mixture of gas and air is passed through a perforated plate of platina, or a tissue of platina wire gauze, by which it is divided into numerous small jets. The minute jets pass through the interstices of the platina, and are ignited. The metal soon becomes incandescent; the supply of air being duly regulated, combustion is made perfect, flame disappears, and the platina or metal becomes a surface of intense light. Sometimes, instead of using a mixture of gas and air, compressed or condensed gas may be used by itself, and air at the ordinary pressure. Sometimes the gas and air may be heated before being burnt, to obtain a maximum effect.—Patent completed.

2350 G. R. V. Loughton and E. B. Jankson, Paris

obtain a maximum effect.—Patent completed.

2350 G. R. V. LOUGHTON and E. B. JACKSON, Paris Composition for bosses. Dated July 27, 1868.

The composition consists of from 60 to 80 per cent. of india-rubber, and 30 to 50 per cent. of pure golden sulphuret of antimony, which are mixed together into a paste. The bosses made of this paste are submitted to a process of vulcanization by the ordinary methods.—Patent completed.

paste. The bosses made of this paste are submitted to a process of vulcanization by the ordinary methods.—Patent completed.

2351 J. Hteeln, Manchester. Printing fabrics. Dated July 27, 1868.

This consists in a new method of making chloride of aniline, or aniline black, by the admixture of sesquichloride of chromium. Instead of combining the aniline with an acid, as at present, when making aniline black printing colour, a solution of a metallic chloride is mixed with it, the base of which is not injurious to the proper oxidation of the aniline. From this means, the aniline combines with the chlorine in definite proportions, and chloride of aniline free from excess of acid is formed. According to the metallic chloride used, the metallic base is in some cases either wholly or partially precipitated, and in other cases no precipitation takes place, a liquid being obtained containing aniline, chlorine, and the metall. The sesquichlorides of iron and chromium are most suitable for this purpose, of the following proportions.—100 parts by measure of aniline of commerce, and according to the saturating power of the aniline from 250 to 250 by measure of asolution in water of sesquichloride of iron, containing iron equal to twelve grains of peroxide of iron, in 100 grains measure. When operating with sesquichloride of chromium alone, the following proportions are used:—100 parts of measure of aniline of commerce, and from 400 to 450 parts by measure of a solution of esquichloride of chromium in water, marking 50 deg, on Twaddell's hydrometer. These mixtures may be used in place of the chloride of aniline employed.—Patent completed.

2352 J. LEWIS, Preston. Consuming smoke. Dated July 27, 1868.

This consists in procuring oxygen gas from any oxygeneous compound by passing a current of steam through a retort charged with such compound, and thence by pipes through or under a fire or hot air chamber, thence to the bridge of a furnace, or at the back of any fire, when a volume of unconsumed carbon has to pass, such oxygen ga

takes place.—Patent abandoned.

2353 C. J. LAURENDEAU, Paris. Saving life. Dated July 27, 1863.

This apparatus is composed of a quantity of thick cork sufficient to float and sustain a person in the water, and is adapted to the abdomen and a part of the chest. A second supply of thinner cork is placed between the shoulders, and reaches to the nape of the neck. This arrangement is intended to produce perfect equilibrium, the part of the body unfurnished with cork acting as ballast. Should the batter desire to swim under water, the collar is removed, or the buoyant part turned from the side of the principal piece, and being furnished with nippers for closing the nostrils and a pipe or tube to breathe through, the end of which terminates in a funnel of cork, so as to float on the surface of the water; and, finally, a person may remain which terminates in a funnel of cork, so as to float on the surface of the water; and, flually, a person may remain and swim a considerable time under water, by making the principal piece of the apparatus both a means of buoying up the body and an air reservoir, from which the bather expels and draws in air by means of a double tube, the reservoir being divided into two compartments by an elastic partition. But this apparatus is intended only for good swimmers, and it would be necessary to carry ballast.—Patent completed.

2354 H. A. DUFRENE, Paris. Indicator. (A communication). Dated July 27, 1868.

The distance mechanism consists of a pulley turned on the nave of one of the hind wheels of the vehicle. This pulley is connected to the mechanism by a round strap passing over an intermediate pulley held by a support underneath it, and passing over another pulley mounted on a shaft adapted to the bottom of the botty of the carriage. On this shaft is mounted an endless screw communicating motion to an indicator. The indicator is adapted to the lower rod of a drum placed on one side of the seat, and on which drum is placed a flat band with a sheet of paper attached to it; the strap is kept fast at the other extremity of the seat by another drum. The seats are divided into places; each place works independently of the other, and all the places are supported at their four corners by springs; on the lower part of the surface of the woodwork supporting the cushion, and at each place, a perpendicular rod with two oblique sides is adapted. When the travellers sit down, the seats descend till they reach fixed points; the rods adapted perpendicularly underneath by means of the oblique side, which is opposite the strap, forces against it pencil rods or needles, and the sheet of paper placed on the strap takes the mark and indicates the distance travelled over by the occupants.—Patent abandoned.

Patent abandoned.

2355 A. V. Newfon, Chancery-lane. Propeller. Dated July 27, 1868.

The propeller consists of a frame, fitted with floats, fixed to axies, which vibrate in journals. When floats are arranged horizontally, they are so adjusted that the lower edge of each float shall rest over the axie of the float below it. When they are arranged vertically, the edges of the float not attached to the axie are adjusted to rest on or against the frame. The propeller is attached or connected to the lower end of a vertical lever, adjusted at the stern sides, or through the bottom of a vessel. The lever may be either made to swing or oscillate on a fixed axie, or be rigidly attached to an axie, made to rock in journals, or be passed through an axie which is enlarged and perforated in its centre. This latter form of attachment is chiefly used to give the vessel a backward motion by reversing the propeller. The lever is operated by a horizontal engine, attached to its upper end. When the lever is set in motion by the engine, attached to its upper an ishorter extremity, the lower and longer extremity carries the propeller backwards and forwards between any two points deemed most favourable to propulsion.—Patent completed.

2356 F. LAMB, A. C. STERRY and J. FORDRED, Rother-backs.

completed.

2356 F. LAMB, A. C. STERRY and J. FORDRED, Rotherhithe. Treating oils. Dated July 27, 1868.

A quantity of oils, fats, or wax, is placed in a suitable vessel, and about 10 per cent. of fuller's earth, in a finely divided state, mixed therewith. These are stirred well together for about thirty minutes, at the same time raising the temperature of the mixture gradually, and maintaining it at about 2004eg. Fah.; it is then allowed to settle, and the oil being drawn off into another vessel is then treated in the same manner with a further 10 per cent. of the fuller's earth. This operation may be repeated until a sufficient bleaching and purilleation has been effected, when the oil may be filtered or left to repose in tanks till it becomes bright and fit for use. In the case of some substances, such as linseed or rapesced oil, where a treatment with sulphuric acid can be used as a means of purilleation, a preliminary treatment with that acid is made. The acid and impurities are allowed to settle down, and the supernatent oil is drawn off into a separate vessel before the addition of the fuller's earth.—Patent completed.

2357 A. M. CLARK, Chancery-lane. Artificial ice. Dated

2357 A. M. CLARK, Chancery-lane. Artificial ice. Dated July 27, 1868.

The water to be congealed is first introduced into one set of vessels, so as to about two-thirds fill them. A disc is then placed on the rim or flange at one end of the apparatus, and a cover applied so as to close the mouths of the vessels; the cover is fixed by a screw. The freezing salt used (such as nitrate of ammonia) is then introduced into the apparatus, with the requisite quantity of water, and another disc similarly provided with recipients placed in position at the opposite end, which recipients are closed by a cover, secured as before-mentioned, so as to hermetically close the apparatus. The apparatus is then set in motion for about ten or a dozen minutes, after which, hollow cones of fee, measuring only two-fifths of an inch in thickness, which deposit on the interior surface of the recipients, are removed, and introduced one in the other.—Patent completed.

2358 C. A. McCurd, Bloomsbury. Swing machines.

other.—Patent completed.

2358 C. A. MCURD, Bloomsbury. Sexing machines.
Dated July 28, 1868.

At the upper part of the frame of the machine is a hori
zontal revolving shaft mounted in suitable bearings; a dise
is fixed to the left hand end of this shaft, having on its
face a stud which works in a suitably formed slot in the
needle slide. At the back of the disc is another stud
which lifts the foot which receives its feed motion from
the edge of the disc. At the right hand end of the shaft
is a wheel with a handle on its face; a link descends from
this handle to a crank fixed to a shaft at the lower part of
the machine. At the other end of this shaft is a vibrating
hook or looper, part of the ring of which is concentric
with the point depressed towards the axis.—Patent abandoned.

2359 W. F. M. GREEN, Sunbury. Loading guns. Dated

2359 W. F. M. GREEN, Sunbury. Locating guns. Distent July 28, 1868.

The object is to perform by machinery the operations of ramming home the charges of muzzle-loading big guns, cannons, and other ordnance, and sponging them out. This is effected by the substitution of a spiral spring, or compound springs, or other arrangement having an equivalent property of expansion and contraction for the rammod or other means as ordinarily adopted. —Patent abandoned.

2360 W. LEWIS, Redditch. Needle wrappers. Dated July 28, 1868

2300 W. Lewis, measurem. Actual w. appear. Date July 28, 1868.

The patentee takes a piece of paper, the same width as the ordinary needle wrapper, and of a length of about one-third greater. One end of the paper is provided with a flap or tongue, made by cutting away the sides of the paper. The blank or paper is divided into three parts, by transverse folds or creases, and the paper is provided with the ordinary longitudinal folds or creases. In the bottom division or part of the paper, and in the middle of the paper, a cross silt is made. By folding the bottom part or division of the paper upon the middle part, a pocket is formed, in which the needles may be placed, and held. The needles are placed loose in this pocket by

being passed through the slit described, the points of the needles resting on the folding edge of the lower part or division of the paper, and the heads and other parts of the needles being exposed on the outer side of the folded part of the paper. The lower part or pocket described may be provided with a flap, by folding down, while the heads and other parts of the needles may be covered. The wrapper containing the needles is folded up in the ordinary way, and is secured in its folded condition, by the flap or tongue, at the top of the wrapper, being engaged in a slit or under a band made in the middle part or division of the paper wrapper. According to another arrangement of this invention, a wrapper is made for holding two or more series of needles in the following manner:—A piece of paper, of about the length of the ordinary needle wrapper, and of a width about double that of the ordinary wrapper, is taken. The paper is divided into three parts or divisions by longitudinal folds or creases, instead of by cross folds, as in the wrapper before described; on one end of the paper a flap or tongue is made. By folding one of the side parts or divisions of the paper upon the middle part, a longitudinal pocket is made, the other side part constituting a side flap, which may be folded upon the pocket. The wrapper thus made is again divided by cross creases or folds into four or other number of divisions, in two or more of which longitudinal slits are made, through which the loose needles are passed. There is thus formed a needle wrapper, in which two or more series of loose needles are held in the same wrapper. The inner folded edge of the pocket described may be provided with a courinnous flap, or two or more flaps, by folding which, the heads and upper parts of the series of needles may be covered. After the needles are put into the several divisions of the longitudinal pocket, when the latter is folded up at its cross folds or creases, and fastened by the flap or tongue at the top, or at one end, being en caged i

2361 H. WATTS, Water-street. Permanent way. Dated

2361 H. WATTS, Water-street. Permanent way. Dated July 28, 1868.
This consists in constructing rails in which a groove is formed in the upper side; into this groove, a strip or length of clastic material is fitted, preferably of vulcanized indiarubber. The clastic material may be secured in the groove by transverse bolts or otherwise. The wheels of the train in passing bear on the clastic material, which tends to deaden the noise ordinarily produced.—Patent abandoned.

2362 E. S. T. STEANE, Barking. Shap. Dated July 28,

In order to manufacture one ton of soap, the patenties bils from lewt, to 2ewt, of oil, grease, or fatty substances, with 2ewt, 3ewt, or 4ewt, of caustie soda lees, for one, two, or three hours, to which is ad led separately. Sewt, 10ewt, or 12ewt, of lime water, from 2ewt, to 3ewt, of sola crystals, 2ewt, to 3ewt, of silicate of soda, from lewt, to 2ewt, of common salt or salt cake, and 4ewt, of nitre cake. The matters are boiled together for quarter or half-hour, lime water being added as the boiling proceeds to compensate for evaporation, and the mixture is then framed and crutched until it sets. By combining materials in the above mentioned manner, a soap may be produced of equal quality to that at present requiring twice the quantity of goods or fatty substances. In order to give wear to the soap, there is added thereto, during the above process, any suitable proportion of animal matter, such as horn or bone dust, integuments of animals, or ground cereals, pulped vegetables, or other suitable substance.—Patent abundoned. In order to manufacture one ton of soap, the patentee

2363 S. HYDES, Sheffield. Heating and cooling. Dated

pulped vogetables, or other suitable substance.—Patent abandoned.

2363 S. Hydes, Sheffield. Heating and cooling. Dated July 28, 1863.

This invention consists, first, in the application of guides or channels, to direct hot gases or fluids to the surface of their containers, such as flues, tubes, ogother channels, for the purpose of more fully developing and absorbing the caloric from the gases or fluids, and using the same for any specified purpose, which caloric would otherwise be lost by passing away through the body or central part of the fluos or tubes. Second, in applying on each or only on one side of a partition (situated between hot and cold), guides or channels, through which air, fluids, or gases are guided in parallel lines, or nearly so, or in cross lines, and in constantly circulating streams which pass instantaneously within the most effective distance over and entirely cover the whole surface of the partition to be acted upon for the purpose of transferring their heat or caloric from one fluid to any other fluid. Third, in passing hot liquids through flues or tubes, and by directing cold air or water against the outer or cold side of the partition, to cool the liquids, and thereby operate as a refrigerator. An upright flue or duct is enclosed, and against the outer surface of one side guides or channels are attached, with openings therein for directing cold air or water against such side surface. Guides are fixed in the enclosed part of such flue or duct, the guides being formed with horizontal partitions across them for arresting the direct passage of the heated air, fluids, or gases, over and through them, and thereby causing them to pass under the edges of the guides, and pass thence against the surface of the cooled partition of the flue or duct, and through and between the other half of the guides, situated at the other sides of their respective horizontal partition and so on through each set of guides, there being several sets fixed in the closed flue. The heat thus collected on the cooled

Patent completed.

2364 J. Webster, Birmingham. Refning metals.

Dated July 28, 1968.

Atmospheric air is forced through or over hydrochloric acid, for the purpose of taking up hydrochloric acid gas or vapour, for application in the manufacture or refining of iron, while in a fluid or molten condition. Also in causing atmospheric air in a cooled or heated state to be forced into or over hydrochloric acid and then through naphtha or volatile spirit, for the purpose of taking up hydrogen and carbon gas or hydrogen and a portion of the carbon from the volatile spirit. The gas is then forced through, into, or over the metals while in a molten state, for the purpose of taking up sulphur, phosphorus, silica, or carbon, or other impurities, which the metal may contain.—Patent completed.

friction to the rollers or beams over or under, which the fabric passes for the take up. The object of another part is to clear the wefts when oscillating shuttle boxes are used. An arm stands out from a rod, carried by one of the swords, or by the framing of the batten, when raised lift one of the wefts out of the way. The shuttle, when the boxes are in one position, acts on the weft of that shuttle, and, when the boxes are in position to hold one weft down, the shuttle of the other passes over it thus the wefts of the respective shuttles will be acted upon correctly by the weft forks.—Patent abandoned.

2336 I BULLDHOU Accident Shuttles Dated Inly 28.

2366 J. Bullough, Accrington. Shuttles. Dated July 28,

This consists in so making shuttles that they shall be free to swivel on centres.—Patent completed.

free to swivel on centres.—Patent completed.

2367 C. A. LA MONT, New York. Preserving segs. Dated July 28, 1868.

This consists in the production of an improved preparation of egg in small thin flakes, scales, or particles, readily soluble in cold water, of a bright clear colour, and fresh pure quality, and which, when dissolved in water, and beaten up, possesses the qualities and characteristics of freship beaten eggs. This new article of commerce may be most readily produced by taking fresh eggs, beating them up thoroughly, and then immediately drying the resulting batter in a thin film upon revolving metallic plates in a current of pure air, heated or not, in a drying chamber. Sulphate of lime or other preservative chemicals not injurous to health, may be added to the egg batter, before drying, to insure a more perfect preservation of the purity and freshness of the prepared egg.—Patent completed.

2363 W. R. LAKE, Chancery-lane. Glue. Dated July 28

2363 W. R. Lake, Chancery-lane. Gue. Dated July 28 1864.

The first part relates to the condition of the glue when ready for sale and transportation, and consists in its manufacture in the form of thin flakes or scales. The second part relates to the means of trying on the fluid or semi-fluid in iterial to be dried, and consists in the employment of plates of porcelain, or surfaces not affected by the scidis in the glue, for the purpose of drying the thin ilims thereon; the plates are dipped two or more times in the liquid, chilling it between each immersion, and thereby taking on a thicker and more uniform coat; also in pouring or throwing the glue upon the plates where it is not convenient to immerse them. The third part relates to means for presenting the glue upon the plates on a carrier, as a wated or belt, to be exposed to drying influences. Also in means for adjusting a series of plates on a carrier, as a wated or belt, to be exposed to drying influences. Also in the employment of delectors, which disturb and deflect the air on the outside of the channel in which the plates are carried; also in the employment of inside deflectors, which disturb and deflect the air on the inside of the channel, these latter deflectors being ordinarily carried on the belt or wheel, and moved with the plates; also in the combination of both outside and inside deflectors, arranged to mutually act on the currents of air, and to agitate and disturb them, and complete them; also in a peculiar construction of the apparatus, by making the flexible part in the form of a chain having rigid links, and by making the pulleys in the form of prisms, corresponding thereto; also in the employment of the sir thus circulated, with or without the employment of hear is also in the manner of employing two currents of air, the one cold for chilling the glue and the other either warm or chemically dried; also in the general combination of a carrier, with glue presenting surfaces, rotating on axes carried thereon, and with drying currents of air.

in a vacuum, or in drying currents of air.—Patent completed.

2369 S. M. MARTIN and S. A. VARLEY, Holloway. Trais signals. Dated July 28, 1863.

The patentees wrap spirally round a soft core of hemp, one or more wires to form a strand; any number of these strands are arranged side by side and bound together; the one or more wires to form a strand; any number of these strands are passed through a bath of melting marine glue. The conductor at one end is connected to a miested plate attached to the wooden face of the buffers; the other end of the conductor is connected to an insulated wire running from end to end of each vehicle. Electric bells are arranged with electro-magnets, the soft iron cores of which, fit into a block of cast iron forming one solid piece with the frame, to which the other working portions are attached. To the pole of one of the soft iron cores a soft iron horn is attached, which forms the extension of the pole; between this horn and the pole of another small electro-magnet, a magnet (by preference a perm ment one) works, which, for distinction, is called the "stopping lever." The small electro-magnet is usually rendered magnetic by induction from a permanent magnet; a striking lever carrying a hammer is attached to the armature, which is attracted by the electro-magnet when rendered active. There is a projecting or stopping piece attached to the striking lever, which catches on the top of the stopping lever, and prevents the hammer striking the belt; if set in motion by oscillation, when the circuit is closed, the electric current reverses the magnetism in the small electro-magnet, repelling the "stopping lever," which is attracted towards the soft iron horn, and gets out of the way of the stopping piece attached to the striking lever.—Patent completed.

2370 A. Morrall, Warwick. Needles. Dated July 28,

2370 A. MORRALL, Warwick. Needles. Dated July 28,

2370 A. MORRALL, WARWICE. Necues. Dated July 28, 1868.

The eyes of the needles are formed in such a manner that the needle having been threaded, the thread may be securely retained in the eye the time the needle is employed in its work. It consists in forming a kind of double eye, or an eye having a double curve, which, from its shape, forms two separate eyes, but connected together, the upper part being nearly round and smaller than the lower part, which is of an oval or loop shape. The needle is threaded in the lower or larger of the two parts, and when the needle is used, the thread or sewing material will be drawn up into the head or smaller part of the eye and be therein contracted. The ordinary tension will be insufficient to disengage the material from the eye.—Patent completed.

over the metals while in a molten state, for the purpose of taking up sulphur, phosphorus, silica, or carbon, or other impurities, which the metal may contain—Patent completed.

2365 G. HODOSON, H. BOTTOMLEY and E. COCKROFT, York. Looms. Dated July 28, 1868.

The object of one part of the invention is to obtain

paid previously marked thereon, or such amount may be marked thereon at the time of payment, as is now frequently the case; the person having such ticket is required to place it in the box or receptacle before mentioned, or to see that it is so placed by the person in charge.—Patent abandoned.

2372 J. SIMPSON, Manchester. Moulding wheels. Dated 29, 1868

2372 J. SIMPSON, Manchester. Moulding wheels. Dated July 29, 1868.

This consists in constructing machines for moulding toothed wheels from a segment pattern. Also in an improved arrangement of the dividing apparatus for moulding wheels with an even and uneven number of moulding wheels with an even and uneven number of teeth, and in an arrangement of graduated slides for determining the diameter of the wheel to be moulded. An iron ring or turntable is litted upon a circular V projection, and free to be turned thereon; there is another ring, which holds a rack with teeth inside and outside, a pinion works on the inner teeth to move the ring round, another pinion grears into the outside teeth, a slide is fitted across the apparatus, a segment of a wheel is placed in the first mentioned ring, a sand floor or base is prepared, and the segment placed on and pressed into it, whereby an impression is obtained. The segment is then removed and turned a given distance, and again pressed into the sand, to obtain a mould for another portion of the wheel. This operation is repeated until the whole of the mould is made. The top edge of the apparatus is divided so that wheels of any number of teeth can be constructed.—Patent completed.

2373 F. Winser, Manchester. Epson salts. Dated

number of teeth can be constructed.—Patent completed.

2373 F. WINSER, Manchester. Epson salts. Dated
July 29, 1368.

In order to make Epson salts, the patentee puts carbonate of magnesia or dolomite into gas purifiers, either
dry or saturated, for the purpose of purifying and freeing
illuminating gas from sulphur and other impurities. Or
he places the magnesia or dolomite in chambers or
furnaces, and introduces into the chambers or furnaces
sulphurous acid gas produced by burning any sulphides or
bisulphides of earths or metals, by which means sulphides of magnesia are produced, which sulphides are
converted into sulphates by any known methods.—Patent
completed.

2374 J. MABSON, Norwood. Cinder sifter. Dated July 29.

1868. A shovel is made in two parts; one part forms the scoop for lifting the cinders and ashes, and the other forms a box into which the ashes are free to enter when the front of the shovel is raised and agitated, a grating being fixed across the shovel through which the ashes pass. To the back of the shovel a bar is hinged, one end of which forms a handle; the other end has a plate on it, which is forced into or enters the ash compartment against the rails of the grating, and retains the ashes in that compartment; when the plate is down, as just mentioned, the cinders may be thrown from the shovel on to the fire, or elsewhere. The shovel is fitted with a fixed handle by which it can be lifted or moved from place to place.—Patent completed.

2375 E. Herring, Beer-lane. Treating mail. Dated

2375 E. HERRING, Beer-lane. Treating mail. Dated July 29, 1863,
The object of this invention is the conversion of saccha-

The object of this invention is the conversion of saccharine solutions into grape sugar, and the precipitation of the albuminous and nitrogeneous matters held in solution during, before, or after fermentation. The patentee puts into a converting vessel such a quantity of sugar cane in a dried and coarsely powdered state, as shall contain 1851b, to 1951b, of dry saccharium, which is about equivalent to the quantity of saccharium matter usually contained in a quarter of malt: water is added which is acidulated by mixing 4lb, of sulphuric acid of about specific gravity of 1843 previously diluted with 2 gallons of water, the temperature being about 50deg. Fah., with or without 4lb, of solution of bisulphide of lime, and the acidulated water being added in successive portions so as to exhaust and dissolve the sugar contained in the various substances, and ultimately to obtain 72 gallons of saccharine solution.—Patent completed.

2376 W. R. Lake, Chancery-lane. Substitute for linsed

—Patent completed.

2376 W. R. Lake, Chancery-lane. Substitute for linseed oil. Dated July 29, 1868.

In order to prepare the compound, the following ingredients are mixed together,—carbon oil, resin, becswax, litharge, gum caoutehoue, and spirits of turpentine. These are mingled in the following proportions:—10 gallons of carbon oil, 151b. of resin, 40z. of becswax, 40z. of litharge, 10z. of the gum caoutehoue, and 1 gallon of the spirits of turpentine. This mixture is compounded as follows:—The carbon oil and resin are mixed together by subjecting the same to heat until the resin is thoroughly dissolved. To this heated mixture the becswax and litharge are added, the becswax and litharge having first been boiled together, and allowed to cool and settle. The gum caoutchoue is then dissolved in the turpentine, which is then mixed with the compound, and the same is ready for use.—Patent completed. completed.

completed.

2377 W. R. LAKE, Chancery-lane. Firearms. Dated July 29, 1868.

This consists chiefly in a novel construction of the firing pin, and in its peculiar arrangement in combination with the bolt and breech shoe, whereby the danger of accidentally exploding the cartridges, either by pulling the trigger or otherwise, is entirely obviated. The invention also consists in the novel mode of preventing the binding or striking of the bolt in its chamber, also in the peculiar construction of a stop, which prevents the accidental removal or escape of the bolt from its chamber, and at the same time allows it to be readily removed when required for cleaning or other purposes: also in the novel arrangement of the parts of an ordinary gun lock for increasing the strength and durability of the same.—Patent completed.

2378 W. R. LAKE, Chancery-lane. Seeing machines.

Patent completed.

2378 W. R. Lake, Chancery-lane. Sacing machines.
Dated July 29, 1868.

This consists partly in the arrangement of a continuous shaft in combination with several discs which produce the motion of the crotchet needle and awl, and the various other parts, in such a manner that an independent motion can be given both to the needle and to the awl, the discs being adjustable on the shaft, each independent of the other, so that a correct motion of the various parts in relation to each other is ensured; also in the arrangement of an independent oscillating needle stock and an independent oscillating awl stock in combination with lever, segments, and toothed quadrants. Either of these instruments can be made to "dwell" or remain stationary at certain stages of its motion, as the nature of the work may require; further, in the arrangement of an oscillating lever forming the bearing for the pivot of the needlestock

In combination with a lever segment and toothed quadrant, in such a manner that by the action of the oscillating lever a motion away from the stationary axis of the awl stock is imparted to the needle stock and needle without throwing the toothed quadrant out of gear with the lever segment; also in the arrangement of a locking lever in combination with the oscillating lever which carries the needle stock. Also in the thread carrier which receives a vibrating and a transversely sliding motion in such a manner that the thread is looped round the hook of the needle without fail, and with perfect regularity. Also in the arrangement of a barb coverer in such a manner that by the action of the said barb coverer the barb of the needle is covered at the proper intervals, thereby preventing the same from catching in the loops on its return strokes; also in the arrangement of a loop guide in combination with the feeder and with the oscilating needle; in the arrangement of a spiral spring and stop working on the periphery of the awl shield and stop working on the periphery of the awl shield and stop working on the material. Also in arranging the needle and the needle shield in such relation to each other that when the needle is in its outer position, to draw the loop tight, its hook or barb is entirely inside the shield, thereby holding the needle steady, and preventing the loop from getting out of the barb; further, in the arrangement of a rising and falling lever, and of a transversely oscillating lever in combination with the feeder. Also in the arrangement of a stop motion.—Patent completed.

2379 A. V. Newton, Chancery-lane. Polishing powder.

2379 A. V. NEWTON, Chancery-lane. Polishing powder. Dated July 29, 1868.

The powder, more or less coarse, which forms the subject of the present invention, is obtained from bauxite. The powder of bauxite, placed in a suitable vessel, is steeped in concentrated acid and heated to a temperature of from 104deg. to 122deg. Fah.—Patent completed.

of from 104deg, to 122deg, Fah.—Patent completed.

2330 J. R. Harper, Clerkonwell. Telegraph cables. Dated
July 29, 1863.

In order to carry out the invention, the patentee casts
zinc or its alloy after being rolled into a cake or plate
which is cut into strips by means of a circular saw. The
strips, after being annealed, are then drawn through a die
so as to partially reduce them, and any burrs or ragged
edges produced by the drawing process are removed. The
annealing and drawing processes are then repeated, the
burrs being removed between each process, when necessary, until the bar of zinc or its alloy is reduced to the
form of a wire of the size required. The wire is employed
in the manufacure of telegraph cables.—Patent abandoned.
2381 J. RADCLIFEE Durham. Steam hammers. Dated

2381 J. RADCLIFFE, Durham. Steam hammers. Dated

2381 J. RADCLIFFE, Durham. Steam hammers. Dated July 29, 1868.

This consists in employing two steam cylinders, made to act in such a manner that, when the piece of iron under operation is pushed to one side of the anvil by the piston of one cylinder, the mass can be lifted by the other cylinder to enable the workman to turn and hold the mass in any position.—Patent completed.

der to enable the workman to turn and hold the mass in any position.—Patent completed.

2382 H. O. ROBINSON, Glasgow. Dredger. Dated July 29, 1868.

This consists of a helical or spiral cutter placed in and revolving in a cylinder, and driven by a shaft or prime mover. Attached to the upper end of the cylinder is a tube through which the dredged material, mixed with water, passes or is driven upwards, to assist which small screw propellers are made to operate within the tube. The cylinder, with the spiral cutter and tube, is placed in a floating vessel in an inclined position, and the spiral cutter is urged against the bottom by drawing forwards the vessel in the usual way.—Patent abandoned.

2333 S. C. LISTER, York. Cutting pile fabrics. Dated July 29, 1868.

This consists in so arranging the cutting instrument that it shall cut only in one direction. This may be accomplished by causing the slide or race in which the knife moves to recede so that the knife shall be out of action whilst moving in one direction. Another part consists in weaving pile fabrics face to face in the grey, that is, in the undyed state, and subsequently dyeing them as hereinafter described. In weaving silk velvets, the pile yarn has always been dyed on account of the difficulty of dyeing such goods after being woven without injuring the pile. Cotton velvets, such as are made at Manchester, are woven in the grey, and then the pile loops are cut by hand, but as the pile of these goods is not woven to stand upright, but is a sort of bastard pile or nap, there is no difficulty in dyeing and finishing them. For dyeing and finishing silk and cotton velvets woven in the grey as above described, they are subjected to the dyeing process whilst held distended, so that they may be dyed and finished without handling. This is done by fixing or extending them on a wheel of equal circumference to the length of the piece. The wheel with the velvet is then placed in a dyeing vat, and slowly turned until the velvet is properly dyed; the wheel is then rem

brushing frame and thoroughly brushed, which greatly improves the velvet.—Patent completed.

2384 J. JEFFREYS, Norwood. Preserving food. Dated July 29, 1868.

The patentee constructs a long rectangular tube on a steep inclination. It is divided by longitudinal and upright partitions into passages alternately narrow and broad. Up the narrow passages and down all the broader passages a chilling current is forced. Flat oblong cases, charged with the matter to be frozen, are slid edge forward on rollers into the bottom of the passages. The lowermost row of cases forming the front ones of each long tier are, when hard frozen, let out of their passages by a trap door under the trunk, which, in falling, raises its hinge end to stop the descent of the tiers behind, and is closed instantly that the front row of cases is discharged. The tiers then slide down a stage, the foremost cases occupying the position of those discharged. A fresh set is then introduced into the furthest and upper extremity of the trunk. Thus the chilling currents, as they ascend, draw heat from the cases in succession, and before leaving the trunk, become nearly as warm as the uppermost row of cases. At the same time, the cases in descending fall in temperature when in its nascent state. Thus the two important principles of gradative heat conduction and continuous operation are effectively established.—Patent ompleted.

2385 J. WOLSTENHOLME, Lancaster.

2385 J. WOLSTENHOLME, Lancaster. Valves. [Dated July 30, 1868.]
This consists in constructing the valves for admitting steam to an engine cylinder, and for discharging the exhausted steam. The valves are cylindrical; they cover and uncover the ports leading to the steam cylinder, and to each valve is cast a semicylindrical projection which alternately covers and uncovers the exhaust ports. There is also a passage through the semi-cylindrical projection to allow a portion of the exhausted steam to escape before the lip of the valve uncovers the exhaust port, thereby allowing the valve to complete its traverse. The valves are moved to and fro by an arm on the piston rod acting on adjustable shoulders fixed to the valve spindle. By this arrangement the valves are placed near each end of the cylinder. The steam passages are reduced in length, and consequently steam is economized.—Patent abandoned.

and consequently steam is economized.—Patent abandoned.

2386 G. WOODHOUSE and J. G. M'MINNIES, Lancaster.

Buildings. Dated July 30, 1868.

This refers, first, to the construction of buildings in which arches are required. For this purpose, girders stretching from "bay" to "bay," or other such division or compartment, are employed, and from these girders arches are sprung; another part consists in forming the arches of tiles, brick, or similar moulded article, manufactured to the required shape and dimensions in one piece, or in two pieces, with the addition, if desired, of a central portion or key. Another part consists in the use of cast-iron beams and wrought-iron girders. The beams extend across the building, and are supported by the walls, with intervening pillars. Upon these beams, and below their top surface, steps or brackets are formed, for the reception of the ends of the girders, which are then secured to the beams by angle irons.—Patent completed.

then secured to the beams by angle irons.—Patent completed.

2337 A. WATKINS, Covent-garden. Watches. Dated July 30, 1868.

The pillar plate on which the dial is fixed is formed out of a solid piece of metal, curved on the edge, so as to admit of it being fastened into the case, without the use of screws. It has recesses formed or sunk on its under surface into which the barrel and ratchet are placed, whereby the necessity of employing several separate parts to carry the same is avoided. In order to dispense with the use of a chain and fusee and the multiplicity of parts connected with the same, the power is applied directly to the centre wheel by means of a box or barrel containing the main spring. The main spring is tapered, both as to its depth and thickness, with a peculiar tapering on the latter. This is done in order that it may properly free itself and prevent biting in unwinding, whilst the narrow outer end is one-third thinner, in order to give the necessary elasticity. To allow of the spring being wound up and at the same time held in its required position when so wound, without the use of springs to retain it in position, a self-acting click is employed. This click is placed underneath the barrel in a recess or sink in the pillar plate which is provided for the purpose, whereby it is free from any liability of becoming clogged or impeded in its action by dirt. This click is soformed that in winding up it keeps out of gear or free from entering the teeth of the ratchet, and by means of a projection on the inside opposite the part which enters the teeth of the ratchet, and which is touched by the teeth of the ratchet in passing when the winding is finished, the locking end is caused to enter the teeth, and as hold the spring in the proper position.—Patent completed.

2383 C. H. Rockner, Whitchurch, Hants. Paper.

2388 C. H. ROECKNER, Whitchurch, Hants. Paper. Dated July 30, 1868.

Dated July 30, 1868.
This consists, first, in placing an endless cloth under the wirework where the stuff enters upon it, and by this means retaining the water in the stuff when it flows upon the wire. Second, suckers or wipers are placed under the wirework to wipe the water off from its under side. Third, where a dandy roller is used, a sucker inside it is used to take up the water which enters through the roller and discharge it at the end. Fourth, india-rubber is employed to form the surface of the coutch rollers.—Patent abandoned.

Is employed to form the surface of the coutch rollers.—Patont abandoned.

2389 S. C. Lister, York. Weaving face to face. Dated July 30, 1868.

According to this invention, the silk yarn of which the pile is composed is so prepared that the knife which severs the pile shall break, or partially break, asunder the silk instead of cutting it cleanly, and so leave the surface of the pile uneven, and although this unevenness is quite imperceptible, yet the richness of colours of ordinary hand-cut velvet will result from it. In addition to thus preparing the silk yarn or "schappe," it is also required to remove from it any matter that may blunt or wear the edge of the knife, that is to say, that the silk yarn or schappe after being dyed should not contain anything else than the colouring matter, and that all extraneous matter shall have been completely purged out from it, especially greasy or incidulous matter, for both of these act to blunt or wear the edge of the knife, a bath of muriatic acid. of a strength of about 8deg., is made. The yarn is first passed through a bath of pure water with the object of wetting it evenly, after which it is wrung; it is then placed in the acid bath and left submerged for a time, varying with the temperature and with the fineness of the yarn, and also with the dyeing process, to which it has afterwards to be subjected to.—Patent completed.

has afterwards to be subjected to.—Patent completed.

2390 T. H. ROBERTS and B. C. CROSS, Plymouth.

Stopping carriages. Dated July 30, 1868.

The patentees fix each brake block to one end of a short lever, the opposite end of which is pin jointed to the bar. Stops are fixed to the bar to prevent the blocks descending below the bar, so that if the carriage is moving forwards and the blocks are applied to the wheels, by reason of the speed of the horses being reduced, the blocks are drawn downwards against these steps, but if the carriage be at rest, and the horses are backed, the brake blocks will by the back rotation of the wheels be lifted up away from the stops, and thus the wheels will be left at liberty to turn freely. Stops are also applied to prevent the brake blocks from being too much raised, and also to prevent the brake bar from moving too far back when backing the carriage.—Patent completed.

2391 G. DAVIES, Lincoln's Inn. Printing plates. Dated

2391 G. DAVIES, Lincoln's Inn. Printing plates. Dated

July 30, 1868.
A positive or negative of the object desired to be reproduced (whether a picture, landscape portrait, or other subject) is to be obtained in any known manner. The next process is to place behind this positive or negative a sheet of glass, either ground, lined, or otherwise marked

with any design, or wire gauze, woven fabric, or other substance capable of giving by transmitted light the appearance of hatching or grains, square or round stippling, or other desired effect: a photographic proof is taken therefrom by transmitted light, or the photograph of the grain or hatching may be taken first, and then placed behind the photographic plate to be reproduced. When the photographic proof of the subject, with the hatched or stippled effect, has been obtained, a very thin coating of bichromatized gelatine is to be poured carefully over the surface to impregnate the collodion therewith. After desiccation it is exposed to light, and then immersed in water. The image or picture is represented by reliefs and depressions. A cast can then be taken in metal, which can be used for printing.—Patent abandoned.

2392 G. DAVIES, Lincoln's Inn. Electric battery. Dated 30, 1868

July 30, 1868.

This consists in an arrangement of metallic bars of dissimilar metals so arranged together as to constitute a very compact yet powerful and constant pile, without cloths or any other porous substance essential in the construction of the voltaic pile, and without caustic acids, as employed in galvanic batteries. The several bars are made of two or more metals, and fixed in a regular alternating series, as, for example, one bar of zinc or zinc magnesium is soldered at its ends to the next bar as its fellow, which bar may be of copper, brass, or yellow metal, and then this pair is insulated from the next pair by rubber, glass, or gutta-percha, and so on through the whole series contained in the battery frame holder.—Patent completed. Patent completed.

2393 J. Duguid, Glasgow. Dressing flour. Dated July 30

1868.
This consists in covering the drum of the machine, in which the flour is finished or dressed, with wire gauze, instead of with silk, as hitherto, whereby economy at first cost and durability of the dressing material or fabric are obtained. The wire gauze may be attached to the drum in the same manner as the silk is at present, or it may be stitched, nailed, or affixed thereto in any other convenient manner, and is used in exactly the same way as the silk at the same time obviating the necessity of internal machinery for the forcing or brushing through of the flour.—Patent completed.

Patent completed.

2394 J. RAWSTHORN, Preston. Dressing millstones. Dated July 30, 1868.

This consists in using a hollow cap or post secured by a boit or otherwise in the centre of the stone to be dressed, and above its surface, and in mounting upon this centre post a bed or frame, which, while resting upon the surface of the stone, can be turned round the post as a centre, and can be secured to the post in any required position. In the bed or frame a horizontal slide is arranged to slide in the direction in which the cuts have to be made in the face of the stone. This slide is moved by a screw, so that the cuttung tool can be advanced after each cut, the cuts are made parallel to each other. Upon end of the horizontal slide a way is formed in a direction at a right angle to the first-named slide (the two parts forming a T), and upon this slide way, the face of which is vertical, a second horizontal slide is mounted which can be moved to and fro by hand in the line in which the cut is to be made. To this second horizontal slide a bracket is fitted to slide vertically, and this slide is adjautable by a screw, to regulate the depth of the cut. The pick or cutter is secured to one end of an arm or spring; the other end is carried by a pin or fulcrum in the bracket and the tail of the spring, or a spring pressing upon the arm is acted upon by an adjusting screw (also carried by the bracket or vertical slide part), which screw regulates the force or elasticity of the blow. The end of the pick arm or lever moves in vertical guides or slides to prevent lateral vibrations, and the plane of its movement is parallel with the line of the cut: it is lifted by a can working upon a stud, fited in the bracket or vertical slide part, or upon a shuft tin a bearing formed therein, which cam acts as a stop to prevent the pick from going too deep. Thus the pick is lifted by the cam, and it is forced down to give the blow by the spring—Patent completed.

2395 J. H. JOHNSON, Lincoln's Inn. Gas flame spreader

2395 J. H. JOHNSON, Lincoln's Inn. Gas fame spreader. Dated July 30, 1868.

This consists of a thin metal plate, which may be made in the form of a yoke or horse-shoe, connected at its ends by a curved cross-piece, and having two curved flexible arms extending at opposite sides from the vertical portions of the plate, which clasp or grip the tip of the burner and retain the plate thereon. The curved or arched portion of the plate is made sharp at its inner edge, and its outer edge has a V-shaped groove formed around it. The plate when applied to the burner is brought to a position directly above the usual slit in the tip, and is so adjusted that when the gas is ignited all, or nearly all, the luminous portion of the flame will be above the upper edge of the plate. As the flame strikes the inclined sides of the plate it is spread or distended while the air passes from below the flame into the V-shaped channel, and through the latter to the centre of the flame, which is thus furnished with such a plentiful supply of oxygen as will ensure a perfect combustion and produce a flame of great brilliancy.—Pattent abandoned.

2396 T. Prosser, New York. Distilling. Dated July 30.

2396 T. PROSSER, New York. Distilling. Dated July 30,

1868.
This applies to the production and condensation of steam This applies to the production and condensation of steam in connection with the steam engine. To alcoholic distillation, as well as to the production of fresh from the sea or other impotable water. Also to the production of salt from brine, and of sugar from syrup, and to other uses. For this purpose, the liquid to be evaporated is contained in a close receiver, in the upper part of which is placed a series of chambers, communicating with each other, and through which a heating medium, as steam, het water, air, or gas, is successively caused to flow, by which evaporation of the liquid in the receiver is effected. The vapour obtained may pass down a tube into a chamber, which may be called a condenser, and thence into another chamber, which may be called a refrigerator, both contained in the receiver, or the vapour obtained may pass away to act as a motive power, and thence be brought book to the condenser and refrigerator for use or re-use as the case may require.—Patent completed.

2397 J. C. HADDAN, Westminster. Cunnon. Dated

vent or touch hole made in the gun itself, or made in a plug or stopper, fitted into the gun, forming in the one case the vent itself, in the other, the plug hole, with the inner end next to the bore of a trumpet-mouthed shape, inner end next to the bore of a trumpet-mouthed shape, which it is believed will prevent, in a great measure, the cracks which so frequently occur round the lower part of the vent or plug hole, and which result in the bursting of the gun. For this purpose, the patentee removes from the gun so much of the edge at the entry or junction of the vent and of the plug hole into the bore of the gun as may be necessary for the purpose, and when the vent is bouched, the plug is made to terminate at a distance, somewhat short of instead of penetrating completely to the bore of the gun.—Patent abandoned.

short of instead of penetrating completely to the bore of the gun.—Patent abandoned.

2398 J. and H. A. Gwynne, Hammersmith. Pumps and condensers. Dated July 30, 1863.

This consists, first, in the construction of centrifugal pumps, by making the impeller without the usual discs or side plates. Second, in order to vary the speed between that of the engine shaft and the centrifugal pump, the frictional wheels are formed with one square or angular-shaped groove, in the one and corresponding projection, upon the other fitting rate the groove, the amount of friction between the wheels being regulated in the following manner:—The wheel with the groove is divided into discs, one of which is provided with a boss on which a thread is cut; when in working order, these discs are separated from one another a short distance, and held in that position by a metal nut; this nut is circular in form, and the periphery is cut into a ratchet wheel; when from any cause it is required to vary the amount of friction between the wheels, the ratchet nut holding these discs is tightened or slackened accordingly; a pawl and catch is attached to one side of the disc to prevent the ratchet increasing. For the purpose of condensing the exhaust steam of an engine, the suction or delivery pipe of the pump is made for a certain portion of its length of thin metal; this length is enclosed within a casing of greater diameter, so that an annular space or chamber forms a condenser for the exhaust steam from the cylinder of the engine, which upon being caused to puss into it is immediately condensed by contact with the cold metallic surface, maintained cold by contact with the cold metallic surface, maintained cold by contact with the cold metallic surface, maintained cold by contact with the cold metallic surface, maintained cold by contact with the cold metallic surface, maintained cold by contact with the cold metallic surface, maintained cold by contact with the cold metallic surface, maintained cold by contact with the cold metallic surface,

2399 W. C. FIDLER, Isle of Wight. Railway rolling stock. Dated July 30, 1868.

Dated July 30, 1868.

This consists of arrangements by which the main frame of a railway carriage is carried upon three independent trucks, each of which has one or more axies and pairs of wheels. The three trucks are so connected together so as to be able to adjust themselves laterally to the curvatures of the rails, the axie of each truck being at the same time maintained in a line, radial to the curve traversed, or nearly so.—Patent completed.

time maintained in a line, radial to the curve traversed, or nearly so.—Patent completed.

2400 C. D. Fox, Spring-gardens. Repairing rails. Dated July 30, 1868.

This invention relates to the manufacture of rails, wings, crossings, points, and other iron, of the permanent way of railways, from old rails, or other iron, to the means of improving and repairing rails, and to the machinery to be employed for such purposes. These results are effected by the use and application of dies on rolls in the form of rings, in order that they may be easily removed and changed to forge rings of different kinds and patterns. When the dies are in hammers, they are be cut into segments and are provided with an ordinary dovetall in order that they may also be changed. In operating on old rails, they are cut into two or more lengths, and made into a faggot or pile for the purpose of making new rails, and a plate of Low Moor iron is added to form the head, the whole being afterwards subjected to the action of rolls capable of rolling on four sides at once, whereby rails are produced without first rolling flats. To repair bruised or broken rails, weights and levers are brought to bear on the rolls, to give the requisite pressure, so as to forge perfectly the bruised or broken part. The rail having been cut to its length by a circular saw, and its ends being the weakest parts, they are to be strengthened with steel or other suitable metal, in order that the fibres of the iron rail shall be prevented from spreading; this is effected by placing them in a die, the exact shape of the rail, such die being in two divisions, so that it may be opened and closed. The point of the rail is heated to a welding heat, and also the steel or other metal, when both being placed in the die, the weld is instantly made by pressure.—Patent completed.

2401 W. T. ROYLE, Manchester. Folding paper, &c. Dated July 31, 1868.

2401 W. T. ROYLE, Manchester. Folding paper, &c. Dated July 31, 1868.

The object of this invention is to fold the paper into the form ready for its being made into pattern cards, and in order to accomplish this the paper must not only be folded backward and forward, but must at the same time be pressed or creased so as to allow it to retain the folds. According to this invention the patents amplices. pressed or creased so as to allow it to retain the folds. According to this invention, the patentee employs two pairs of jaws or clamps, pressing and retaining a length. Between these two pairs of jaws or clamps are blades mounted in a frame, to which a reciprocating motion is imparted. The paper to be folded is wound in a roll and placed upon a creel, the end of the paper passing between rollers and also between the blades. On reciprocating motion being imparted to the blades, it moves against the paper, causes it to be unwound from the roll, and conveys it towards the jaws, the other blade moving out of its way to allow it to approach the jaws which, being opened, permit the paper to be placed between them. The blade then retreats, leaving the fold of paper in the jaws,—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT.

Dated February 9, 1869.

THE

# MECHANICS' MAGAZINE.

LONDON: FRIDAY, FEBRUARY 26, 1869.

RECOVERY OF SODA VERSUS RIVER POLLUTION.

ROR several years past the question of river pollution has been a source of considerable trouble to the paper trade gene-The enormous increase of waste lyes, highly charged with chemicals and colouring matter, since the general adoption of esparto grass and the consequent proportionate increase of pollution, as the readiest means of disposing of such waste lyes, has in many localities led to serious and costly litigation. The results have invariably proved adverse to the paper manufacturers, who have been compelled to adopt means for keeping the waste lyes, resulting from the boiling of this fibre, out of the streams. Naturally, these means, so long as they have no other object than to prevent pollution-no matter at what trouble and pecuniary sacrifice to the manufacturers-are looked upon as foreign to the trade and as a necessary evil accompanying the employment of esparto. Hence, very little or no attention is given to the process. The whole thing was and is disliked, and as long as this state of things continues, as long as no other but a negative result is to be attained, nothing else can be expected.

The matter, however, assumes a different aspect when the manufacturers can be convinced that this nuisance may be converted into a source of considerable profit; that, quite apart from the question of pollution, the recovery of the soda from the waste lyes is a commercial and manufacturing necessity, not foreign to the manufacture of paper, but closely allied and essential to it, especially so in the present state of the paper trade. More than one proof that this can be done by adopting proper and efficient means, has been put into the hands of the paper trade, in the shape of various methods of and suggestions for recovering the soda, and for making this recovery process a source of profit. Scarcely any method can fail in causing some profit to be made, when carried out and conducted with an ordinary amount of care. The only question is, which of the various processes suggested is the most rational and practical, and will yield the largest nett profit, without giving offence in other respects? We will giving offence in other respects? pass over the numerous ingenious proposals which have been made, but which have entirely failed, when put to the practical test, and confine ourselves to discuss briefly those methods, the main principle of which may be regarded as correct.

This main principle is throughout the same as that which has been followed for a number of years in the recovery of soda from similar waste lyes at bleach works, and also in mills where straw is extensively used in the manufacture of paper. It is simply evaporation and incineration, and the degree of success depends upon the quality of the fuel employed and upon the construction of the apparatus. The fuel must of necessity depend upon price and local circumstances. We therefore merely mention that, if obtainable, the socalled small, slack or dross from a good coking coal, such as the Durham coal, and that from the Wigan district, is the most suitable for the purpose. The old system of recovery is to heat a hearth or roaster (an ordinary reverberatory furnace with a dished bed for holding the waste lyes) by a strong fire, and

positions. The waste lyes are run or pumped into the concentrating pan or pans, whence they pass into the hearth or roaster. Here they are evaporated down to a solid burning mass, and this is withdrawn into barrows, to be operated upon in some separate calcining furnace, or to be left to burn itself in a heap, either in the open air or in some sort of vaulted chamber or kiln. The soda recovered by this system fuses together in the heap to a solid rock, which requires to be broken up with heavy hammers and steel wedges, and, as we have witnessed in one or two mills, is further reduced by Blake's stone breaker, being finally ground in a mill. quality of the product leaves nothing to be desired, and its action, in the form of caustic solution, is as strong as that from fresh soda.

On carefully examining the system, we find, however, several serious faults (assuming that otherwise the construction of the fire and the hearth be correct) which will be patent even to those not conversant with such processes. In the first place, there is the obnoxious smell which is given off by the mass, when withdrawn from the hearth or roaster, and which is due to imperfect and interrupted combustion of the resinous and gummy matters contained in the waste lyes. Second, there is the amount of manual or mechanical labour required to reduce the recovered soda rock to a state fit for lixivia-tion. Third, there is an objection to the application of the waste heat from the hearth or roaster to the surface of the weaker waste lyes in the concentrating pans. The hearth itself is, with the exception of the short time, when the mass is becoming solid, nothing else but an evaporating furnace. The flame is at its greatest heat on entering the hearth at the firebridge. In passing over the boiling lyes it becomes saturated with steam; in proportion to the distance from the fire-bridge the heat decreases, and with it the faculty to take up or hold steam, so that, if the series of concentrating pans heated by this moist waste heat were sufficiently long, the entire quantity of steam raised in the hearth or roaster would be condensed again in those concentrating pans. Fourth, if the solid and burning mass is kept longer in the hearth than otherwise required, either for the purpose of reducing the stench by giving more time, and so to ensure a more perfect combustion of the obnoxious gases, or for the purpose of getting more evapora-tion in the pans, it is done at the expense of fuel, time, and labour. Fifth, and lastly, there is a drawback in the very considerable resinous and gummy sediment which forms in a very short time in concentrating pans heated by surface heat, and which is owing to the lower portions of the lyes in them being nearly cold.

Though we acknowledge the soundness of the principle of surface evaporation for these waste lyes, we consider that in this old system it has been carried to an extreme, and that the results cannot be as favourable as those produced by the system of construction which has been patented by Mr. C. Seitz, of Broomieknowe, Lasswade, N.B., in which system we find a judicious combination of surface and bottom heat. There is great danger of burning the plates in applying bottom heat to wrought-iron pans, containing, as in the case under consideration, lyes liable to form pasty or solid sediments. If, however, due care is taken that the plates are not exposed to any dry heat or flame, but that steam is always present, no such danger exists, as we then have really nothing else but superheated steam. The principles of this new system, which, we understand, has been carried out at several paper mills with complete success, are,-first, to carry the waste heat from the hearth or roaster, saturated as it is with steam, through an open concentrating pan, by means of segmental flues, passing away to to pass the waste heat over a concentrating pan or a series of pans, placed in various pan and then into the chimney. By this tion.

means, every trace of heat is effectually used for evaporation. Second, to place a reverberatory furnace in such a position that its bed directly communicates with the hearth or roaster by means of an opening. This furnace carries two concentrating pans above its arch, so constructed that they are supported independently of the brickwork, and, in case of repairs, the entire furnace may be taken down and rebuilt without disturbing the two pans.

The furnace is used for manufacturing soda from saltcake or sulphate of soda, in quantity just sufficient to make up the deficiency between the weight of soda recovered and the weight of soda required for boiling the grass. This deficiency varies from 15 to 35 per cent., owing to the unavoidable loss arising from cooling and washing the boiled fibres. quantity of soda required to supplement the deficiency does not keep this furnace fully employed, and during this spare time it is used in connection with the hearth or roaster in the following way:—When the liquid mass in the hearth becomes pasty, and just begins to burn, it is moved through the opening before referred to into the furnace, and is here well worked and turned over, under a low heat, so that every part is thoroughly exposed to the action of the air, which enters through the firebars and door. Thus perfect combustion is insured, and no obnoxious gas -the product of imperfect and interrupted combustion-is allowed to escape unburnt. When the whole mass is at a uniform dull red heat, it is withdrawn for further treatment, The product is a darkish grey powder, as readily soluble as ordinary alkali or soda ash, and contains on an average 44 per cent. of By removing the mass out of the hearth in a yet unforward state, for further treatment by waste heat in the furnace, the hearth is at once at liberty again, for its proper object, evaporation; and thus time, fuel, and labour, are saved, besides avoiding every possibility of bad smell.

Third, the waste heat from this auxiliary furnace, as it may be termed-whether from the manufacture of soda, or from the burning of the recovered soda—is dry, that is to say, it contains no steam, and, therefore, is passed over the waste lyes in the pan immediately above the arch. Here it saturates itself with steam from the under pan, at the same time heating the bottom of the open top pan with moist heat. Fourth, any heat that may still be left after passing between the two pans above the auxiliary furnace is, previous to passing away to the chimney, conducted, together with the waste heat from the hearth or roaster, through the same concentrating pan as referred to under the first head, or through an additional pan of similar construction.

Having described the system, we will now draw attention to the advantages which are found by Mr. Seitz to result from its practical application. In the first place, the amount of fuel, in proportion to a certain bulk of waste lyes or a certain weight of ash recovered, is reduced to a minimum, and every practical heating effect from it is utilized. Next, the working capacity of the plant (furnaces and pans) is exhausted to the fullest extent. Every possibility of bad smell is avoided, and the ash recovered is readily soluble without further treatment, and yields a clear bright solution.

Lastly, leaving the profit of the self manufacture of the deficient quantity of soda out of the question, the waste heat from this part of the process gives a large increase of evaporating power at no expense.

We have gone more fully into the subject than we intended, but the question is of such importance to the paper trade generally that we could not refrain from ventilating the various points on all sides; and now leave the matter in the hands of the paper manufacturers for their serious considera-

# MANUFACTURE OF CAPS AND CARTRIDGES.

No. IV.

HAVING described the manufacture of the external portions of the caps and cartridges, we have now to direct our attention to their actual contents, or what constitutes their peculiarly deadly and destructive properties. We commence with the contents of the caps, consisting of a fulminating preparation. This compound has for its base or principal ingredient the well-known substance fulminate of mercury, usually prepared in the laboratory by the action of nitrate of mercury upon spirits of wine. The reaction gives rise to the compound in question, which is chemically a combination of the protoxide of mercury with cyanogen, and is represented by the formula Hg O, Cy O. During the process, the gases, which are principally of the nitrous and nitric acid type, are condensed, and are given by the formula C 4 H 5 O, NO 3, and C 4 H 5 O NO 5. The chemical formula for pure alcohol is C 4 H 6 O 2, or C 4 H 5 O + HO, and can be evidently deduced from the above by merely substituting one atom of water, or HO, for the nitrous and nitric acids respectively. If instead of NO 3 and NO 5 in the formula for the gases, we write Ho, we arrive at once at the conclusion stated. the establishment of M. Gevelot, the manufacture of this dangerous but necessary compound is carried on during the space of eight days in each month, which is sufficient to supply the workshops for about thirty days, and at the same time maintain a small stock in hand. The preparation of the full minate is thus conducted. Into each of twelve large glass retorts is poured exactly seven pints of nitric acid, NO<sup>5</sup>, to which is added 2.34lb. of pure quicksilver. The retorts are then placed in a small open furnace, and in a short time vapours of hyponitric acid gas commence to "come over." At the end of three-quarters of an hour, the combination of the metal and acid is effected, and its solution complete. The retorts are removed from the furnace, placed upon suitable supports, and another dozen filled with similar materials substituted in their stead. Near to the workshop where this subliming process is executed, are arranged in the open air a series of twentyfive large globular-shaped glass vessels, carefully closed by tightly-fitting corks. Through these corks are passed a number of bent glass tubes, the other extremity of which is attached to one end of an earthenware pipe. The other end of this pipe receives another tube, not of glass, but of pottery ware, which communicates with a large earthenware jar. By means of analogous tubes, this jar is connected with three others, the relative sizes of which are in diminuendo. Into these glass bottles are poured 5.28 pints of the best commercial spirits of wine, entirely free from all essential oil, and carburet of hydrogen. This quantity is immediately supplemented by an addition of the solution of nitrate of mercury, already prepared in the retorts, in the proportion of the contents of one retort for two and a-half bottles. a very short time after these two ingredients are brought into contact, the chemical action commences with vigour. Ebullition sets in, and the bottles are filled with whitish fumes, which pass away by the bent glass pipes, traverse the whole series of pipes and jars already described, and finally escape into the open air by means of the pipe inserted in the smallest and last of them. After a short interval, the white fumes cease and are replaced by the red colored vapours of hyponitric acid gas. At this juncture, another dose of alcohol is added to the contents of the bottles, and the action permitted to continue for another hour or so. No sooner is the necessary time calculated to have elapsed than the

a rapid movement of rotation, cause the precipitated fulminate of mercury to sink to the bottom in the form of a greyish deposit. It is subsequently poured out into the first of three wooden troughs, connected by glass syphon tubes. There it is thoroughly washed to remove every trace of free acid, transferred into another trough and mixed with a certain proportion of nitre, thus completing its com-position as fulminating or detonating powder. In all chemical operations there are invariably a number of waste or bye products produced which are of no real use to the result in question, but, nevertheless, the result could not be obtained without giving rise to them. It is scarcely necessary to remark that endeavours are always made to utilize these products, and not permit them to pass away into the air and become utterly wasted. Let us now ascertain what becomes of the white and red fumes that pass into the pipes and condensers connected with the whole arrangement of the apparatus. Naturally, the gases become condensed in their various receptacles, and a liquid is formed, composed of alcohol ether, and acid. The greater portion of the acid is found in the first condensing jar, while the last generally contains only ether. These bye products are treated with chalk, to remove the nitric acid also carried over with them, and by the addition of an atom of water in the place of the removed acid, reconverted into alcohol, as explained in the formula above. After undergoing the process of distillation, the alcohol is rendered sufficiently pure to be used again in the preparation of the fulminate. As a rule, this is the description of alcohol that constitutes the second addition to the bottles after the escape of the red fumes have commenced, and a double advantage is thereby gained. Not only is the operation of reconversion a cheaper method of obtaining a supply than purchasing it in the market, but the very heavy duty imposed upon the article is avoided, which is at the rate of £28 for every hogshead passing the barrier of Moulineaux. It must not be imagined that M. Gevelot was permitted to enjoy the reward of his chemical skill and assiduity without a little disagreement taking place between him and the inland revenue officers. The authorities contended that in order to deprive alcohol of its liability to a duty, it should be adulterated with some foreign substance, that would render it unsuitable for the purpose of drinking, and, in furtherance of this view, recommended that it should be mixed with a fourteenth part of vinegar, or the essence of terebenthine, or spirit of camphor. Against these propositions, M. Gevelot argued as follows:—He maintained that as the alcohol was required purely as a chemical agent, in the preparation of the fulminating powder, it could not possibly be mixed or adulterated with any foreign substances or solutions, of any description whatever, and that, moreover, as it was not intended to be used as a beverage, it was contrary to the spirit of the law to press upon him a claim for duty. Latterly, M. Gevelot offered to add from two to three per cent. of nitric ether to the alcohol, if he were permitted to use it in his manufacturing operations, but at present no good has ensued from the offer, and the duty is levied as usual.

As will be readily anticipated, from the dangerous nature of the material dealt with, the workmen require no injunctions to fulfil all the precautions that may ensure, so far as human foresight and care can do so, their own safety and that of their fellows in other departments, as well as of the premises in general. The dangers they are exposed to are many and various. In the first place, were any of the liquid to come into contact with their flesh, it would create serious and troublesome hyperactures. serious and troublesome burns and ulcers of a sary time calculated to have elapsed than the workmen, with their hands and bodies protected by thick gloves and padding seize the still smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking between the same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them same precaution is smoking bottles, and by imparting to them smoking bottles, and by imparting to the smoking bottles, and the same precaution is smoking bottles, and the same precau

necessary with all the apparatus and utensils employed. The workmen themselves, although they show no external signs of fear, and evince no trace of undue anxiety, yet plainly demonstrate by the care with which they move about, and the delicacy and gentleness of all their various manipulations, that they are fully aware of what might be the consequence of an ill-judged manœuvre or awkwardness. The entire court or yard where the fulminating compound is prepared, is surrounded by a high wall, built of roughly quarried stones. There is no need for us to comment upon the fearful violence and the terrible effects that follow an explosion of any fulminate. In the premises under notice, the most minute pre-cautions are taken to avoid all chance of such a catastrophe, and also to limit its effects to a circle as narrow as possible, should it ever unfortunately occur. We may now regard the manufacture of the fulminating compound to be complete in the bulk, but there are a large number of secondary operations and manipulations that it has to be submitted to, which are of a nature nearly as dangerous as those already described. All these subsequent processes are carried on in little sheds or cottages, separated from the rest of the premises by strong partition walls of earth and stone, nearly 20ft. in thickness, and, as a further protection, each shed is separated from its neighbour by a nearly similar barrier, so that the subdivision or isolation of the dangerous material is amply secured. These, however, are not the only precautions taken to ward off all risk of an explosion. The ground in the vicinity where the workmen are employed in transporting the fulminate from one place to another, is laid with a per fectly even coat of asphalte or bitumen, so as not to present the slightest roughness or asperity, in the event of any of the explosive compound chancing to fall upon it. The tables upon which it is manipulated are covered with felt, and the legs also rest upon small pedestals, composed of the same material. All the workmen are strictly forbidden to wear any but list shoes, and every utensil and implement used in the minor operations of manufacture are round in form, and have, in fact, no edges. Silence, together with easy gentle movements, upon the part of the operatives, characterizes the whole of their proceedings. A glance is quite sufficient to indicate to the most careless observer that the men are engaged in work of no ordinary nature. Their whole mien and bearing is ample evidence that they are perfectly well aware of the consequence of any indiscretion upon their part. In our next, we shall proceed to describe the manufacture of the fulminating powder constituting the explosive element in caps and cartridges, in which, it has been already stated, the fulminate of mercury plays the chief part.

# NOTICES OF BOOKS.

SMALL heap of sundry volumes at our elbow warns us that time has flown since our last batch of books was despatched, and has permitted another literary accumulation to place us under another obligation to publishers and public. This obligation we now propose to discharge by proceeding to notice the productions in question. And first we will take a new monthly magazine of engineering,\* which has recently been received from America, and which is being brought out by the well-known publishing firm of Van Nostrand and Co. It is conducted by Mr. Van Alexander L. Holley, whose name is well known in connection with a work on Ordnance and Armour. This production, which rejoices in the name of the "Eclectic Engineering Magazine," is a selection from the professional

the ordinary way, by taking whole articles or even portions of them, but by carefully abstracting and digesting them. These abstracts are intended to represent the results of carefully reading a mass of matter, and the object of the work is to save the great body of artizans both time and money in the pursuit of knowledge. The first part came out with the first month of the present year, and its contents lead us to expect it will have a fair run. It fulfils well the part it proposes to take in scientific literature, and will form a useful digest of current engineering practice in America and other countries.

Dr. Lardner's handbooks of natural philosophy are so widely and so well known, that it needs not that we enter into detail respecting the principles of their construction. are everywhere appreciated, and our readers will be glad to learn that a new edition of one of them-that on "Optics," -- has just made its appearance. It has been edited by Mr. Olver Harding, who has kept as closely as possible to the plan of the original treatise. He has introduced such alterations and additions only as were necessary to embody the results of modern investigation, and to bring the work up to the present condition of scientific knowledge. The sections which have undergone the greatest changes are those of the analysis of light, the theories of light, and the application of the undulatory theory to the phenomena of reflection and refraction. To those who desire to attain an accurate knowledge of physical science, without the profound methods of mathematical investigation, we commend this and the other volumes of Dr. Lardner's handbook.

Mr. Burgh has produced a practical treatise on the indicator diagram, which subject he treats very exhaustively. He describes the indicator and its use, and then proceeds to explain the method of taking an indicator diagram correctly. The theoretical geometry of the indicator diagram is then discussed, after which the practical geometry is considered. Indicator diagrams from a number of engines of various classes are given further on, and the little work closes with an explanation of the indicated horse power in connection with the diagram. To sum up in Mr. Burgh's words, "the whole of this is expressed in 164 pages, and illustrated by 100 engravings; so that the entire matter has been fully explained, but not more so than requisite or tiresome." The last eight words convey an impression which must surely be the reverse of what the author intended. However, we will simply say that the sentence is ambiguous, and as Mr. Burgh is much given to ambiguity we will let it pass, observing only that the practical usefulness of his productions is too often marred by the most obscure verbosity. In the present case, with this exception, the work is one which is well worthy of careful study by all who are not familiar with that apparent mystery—the indicator diagram. We have received the Report of the United States Patent Office for the year 1866, from the Commissioner of Patents, at Washington, through the agency of Messrs. Stevens Brothers, of 17, Henrietta-street, Covent-garden, London. This report is comprised in three volumes, the first two containing the text, and the third the illustrations. The report is very comprehensive, and will be found of great utility to all engaged in patent matters in this country. These reports have, hitherto, been somewhat in arrear, but as we received the present volumes only a few months after the reports for 1865, we conclude that in time they will be produced soon after the year to which they refer has closed. This will greatly enhance their value, both in America and other countries. From the Commissioner's

Report, we gather that during the year 1866 there were 15,269 applications for patents, the number issued being 9,450, which included re-issues and designs. There were 2,723 caveats filed, 67 applications for extensions of patents, of which number 58 were extended. The number of patents which expired during the year was 1,042. Of the patents granted, 9,210 were to citizens of the United States, 127 to subjects of Great Britain, 48 to subjects of the French Empire, and 65 to subjects of other foreign governments. The pecuniary position of the office for the year in question was as follows:—495,665,38 dollars were received in fees, the expenditure amounting to 361,724,28 dollars. The amount to the credit of the patent fund on January 1, 1866, was 130,184,78 dollars, which, with the receipts of the year (495,655,38 dollars), gives a total of 625,850,16 dollars. Deducting from this 361,724,28 dollars—the expenditure—leaves 264,125,88 dollars to the credit of the patent fund, on January 1, 1867, the surplus of receipts over expenditure during the year being 133.941.10 dollars. The applications for patents received in 1866 exceeded those of 1865 by nearly 50 per cent., and of 1864 by more than 100 per cent. The number of more than 100 per cent. caveats filed exceeded that of 1865 by nearly 200 per cent. The number of patents issued exceeded that of 1865 by nearly 50 per cent. while that of 1865 exceeded any previous year by more than 30 per cent. The receipts into the patent fund exceeded those of 1865 by more than 42 per cent., while the increase of expenditure was less than 33 per cent.; the receipts of 1865 having exceeded those of any previous year by more than 36 per cent. On the whole, the patent business in America was in a very satisfactory condition at the time of the report, and we believe has since greatly increased. This will have led to enlargements in an already large establishment, to meet the requirements of the department. This is indicated in the Report of the Commissioner, to whom we must give credit for the excellent way in which these reports are turned out, and our thanks for the volumes before us.

Messrs, J. M. Johnson and Sons, of 3 Castle-street, Holborn, have forwarded us a copy of the Report of the Jurors of the Havre volume, which is printed in French and English forms a complete. English, forms a complete history and record of this exhibition, which differed in many respects from those which preceded it. In no previous instances were the various industries, which contribute to the development of maritime progress, so fully represented as at Havre. A novel feature also was the election of the jurors for each class by the suffrages of the exhibitors. official volume before us bears evidence of careful compilation; to ensure accuracy, proofs were submitted to the president and reporter of every class or section. It, therefore, forms a useful book of reference on maritime and commercial affairs, as well as an authentic record of the Havre Exhibi-

That fruitful source of grumbling and frequent irritation, a smoky chimney, has been very copiously dealt with by the Rev. Mr. Ainslie, in a little book just published.

The author treats the subject in a scientific manner, basing his arguments on the well-known laws which govern the ascent of heated air and smoke. He writes from personal experience of the annoyance, and offers the results of his researches into the cause and cure of this evil to the public. Especially do we commend the book to architects and builders, for to their neglect of certain rules necessary to insure a free and regular draught are the public indebted for smoking fires. Of course the right thing is to build the chimney in a proper manner; but if this be not done

in the first instance-and London chimney pots demonstrate how very rarely it is-then comes the question of cure. As smoking fires proceed from various causes so there must be various remedies, and Mr. Ainslie gives numerous causes of the evil, and for each suggests a cure; therefore, those who are pestered with the nuisance in question should consult this book, in which they will not fail to find a remedy let the cause of their fire smoking be what it may. We venture to affirm that Mr. Ainslie will do more practical good by this little treatise in bettering the tempers of those who are afflicted smoky chimneys, than if he had written a sermon double the length upon the faults which have their origin in these irritating nuisances.

We have a batch of small but useful books from Messrs. Cassell, Petter and Galpin, of Belle Sauvage-yard, Ludgate-hill. The first of these is a treatise on orthographic and isometrical projection, the development of surfaces and penetration of solids. It is by Mr. Ellis A. Davidson, and forms one of Cassell's series of technical manuals, of which the first, that on linear drawing, was noticed by us in October last year. The present volume treats of orthographic projection, by means of which objects are projected from given plans, &c., and isometrical projection, by means of which a view of an object is projected at one definite angle, a uniform scale proportionate to the real measurement being retained throughout. The lessons are progressive, and are given in a manner sufficiently simple for all purposes of educa-tion. "Right Lines in their Right Places," is the title of a little treatise by the same author and from the same publishers. teaches the first principles of drawing and design without instruments. This is a novel idea, but it is so well worked out that by following it carefully, children may very easily be taught the rudiments of geometry without the use of any other instruments than a pencil and a sheet of paper. remaining three books from Messrs. Cassell's establishment are also educational, but of the lowest order, in an intellectual sense, being a primary series. They comprise Part I. of a Boys' and Part I. of a Girls' First Reader, and an Explanatory Introduction to Geography. Messrs. Cassell's reputation for works of the foregoing character is so well established that no recommendation from us can add to the value of the books before us, which are in every way fitted for the several purposes for which they are intended. This firm deserves great credit for the good they have effected in rendering education popular.

It is, perhaps, somewhat late to notice annuals, but they were late in reaching us. Of these, three are now before us. is the "Engineers', Architects', and Contractors' Pocket Book," formerly well known as Weale's, but now, and for the last year or two, published by Lockwood and Co., Stationers' Hall Court. The volume for 1869 is, in its general character, much the same as its late predecessors, and contains the usual amount of varied and useful information. The second is an annual which has made its appearance this year for the first time. It is "The Engineers' and Contractors' Office Almanack and Pocket Companion for 1869," and is published by Messrs. Lockwood. It contains memoranda relating to standing orders, railway construction regulation, data and formulæ for wrought-iron girders, steam engines, railways, cranes, roofs, mill-gearing, hydraulics, weight of iron, &c., and has a number of blank leaves for notes and memo-It is a very handy size for the pocket, randa. and will be found very useful.

The third of these annuals is "The Railway, Banking, Mining, Insurance, and Commercial Almanack," which continues to be ably edited by Mr. William Page Smith, and published by Simpkin and Marshall, Stationers' Hall Court. Under the above comprehensive

<sup>\* &</sup>quot;Handbook of Natural Philosophy." By DIONYSIUS LARDNER, D.C.L. "Optics." Sixth thousand. Edited by T. OLVER HARDING, B.A., Lond. London: James Walton, 137, Gower-street. 1869.

title we have one of the most useful almanacks extant, inasmuch as it contains a variety of information on the subjects alluded to as well as the ordinary almanack matter in an extended and interesting form. Mr. Smith gives reviews of the material interests of the United Kingdom for the past year in the form of special articles which possess an interest for all classes of the community.

all classes of the community.

The second volume of "The Percy Anecdotes" has been issued by Mr. J. A. Berger, 13, Catherine-street, Strand, and like the first is a wonderfully cheap production. The present volume comprises a collection of original and select anecdotes of cloquence and patriotism. This series does Mr. Berger credit, and we are sure will prove a great success.

And now that we have cleared off the greater portion of the books on our list, we will relieve our mind of a few ideas which have possessed it for some time past and have been particularly called forth when obliged to stop to cut a thick volume before we could gather its contents. And we cannot better express ourselves than by quoting our contemporary, the "Daily News," on the subject. Says that paper:-" Is it not time that the paper-knife was condemned as obsolete, or classed among the useless ornamental lumber with which our ladies love to load their drawing-rooms? That this is not possible for the reason that books and periodicals are still sold uncut is no slight reproach to the publishing trade, and one which it behoves their customers to bring home. It is the singular conservatism of the members of that trade which makes a paper-knife necessary at all, and we should be glad to know if there be any grounds upon which what seems to be a stupid anachronism can be defended. Why should the onus of completing the mechanical operations which make reading possible be thrown upon those who buy, and why is not cutting the leaves of a book made as much the duty of the binder as sewing them to-gether? It is clear that the act of papercutting can be performed on a large scale at an infinitesimal cost; and that the whole of the uncut books and magazines now issuing from the press are so many encroachments upon the good-nature of the public. For no excuse of difficulty or want of knowledge or of means can be advanced. Too many books and magazines are sent into the world ready for use for any such plea to be received. Still, the example set by Fraser' has been followed by very few of the periodicals; while bulky volumes come before us every day in the year which require an annoving amount of mechanical drudgery to be spent upon them before they are fit for use. are few things more irritating than to be midway in a book of absorbing interest, to have the time as well as the inclination to go on with it, and to be suddenly pulled up for want of any instrument with which to sever its Yet this is happening among us upon leaves. every day in the year. Our booksellers should really condescend to spare us this needless and petty worry, and war to the paper-knife should be the constant cry of every buyer of books." We will only add that they manage these things better in America.

# ELECTRICITY AND TELEGRAPHY.

THE steamer "Investigator," belonging to the Telegraph Construction and Maintenance Company, and having on board the submarine cable for Tasmania, reached the Cape de Verde Island on the 24th ult., all well.

The Submarine Telegraph Company have issued their report, and their meeting has been held. A dividend of 5 per cent. per annum has been declared. Since their previous report, very considerable reductions in the tariff have taken place, and, as is usual in such cases, a very large increase in business has been the consequence: so much so

that during the period of reduction, the amount received for messages has been greater than at any similar period since 1866. The work has been carried on without interruption-a fact due to the number of cables across the Channel owned by the company, but the weather has been such that during the past half-year there were many interruptions at different times to the various cables; so much so, that the cost of repairing them has exceeded the usual amount of £3,000, specially set aside for that purpose. This may be accounted for by the number of cables and the inclement weather causing vessels to drag their anchors and damage the cables, all of which are in anchorage ground; but, on the other hand, we have the satisfaction of knowing that, by reason of the

number of routes, total interruption did not occur. It is very satisfactory to be able to announce the successful recovery of the Cuba and Key West cable, lost during last summer. Sir Charles Bright has at length been successful in not only effecting the recovery of the cable, but in completing the communication between Key West and Havana by this the second cable.

The steamer "New England" (formerly the

"Banshee" of Holyhead and Dublin service), 450 tons, was specially fitted out at New York with the requisite cable machinery. chinery is copied almost entirely from that on board the "Narva," the ship engaged in 1867 in the successful submersion of the first cable. "Narva" was fitted out in 1867 with entirely new machinery, consisting of every requisite, and embracing many novel points, by Mr. F. C. Webb, C.E. In the following year, she was chartered for the second cable, and fitted out precisely in the same manner. On her return to New York, after the loss of the second cable (the one now recovered), careful dimensions of her machinery were taken and drawings made. Similar machinery was made in the autumn and winter, and the "Now England" was fitted out with duplicates of our machinery. Soon after the arrival of Sir Charles Bright at New York, she left for Havana. On the Soon after the arrival of Sir Charles passage she met with very severe weather, and got damaged. The weather was so bad that they had to throw coals overboard. After repairing damages, the work of recovering the cable was trainings, the work is recovering the carlie was much interfered with by the state of the weather. The weather in the Gulf Stream is unlike anywhere else. However smooth and calm it may be, in a few minutes a violent wind will arise, and render any operations for telegraph work im-possible. This may last for a few hours only, possible. This may last for a few hours only, but sufficiently long to mar a day's work. Unfortunately, such weather is almost of daily occurrence, and it is matter of congratulation that the work of recovering the cable has been completed so soon, especially when we consider the disadvantage of weather—grappling in the Gulf Stream, in a four knot current, for a cable resting on an uneven bottom, at about the depth of a mile. However, the cable has at length been recovered, and the communication restored by laying a new piece from the splice to the shore, although not, as originally intended, to the landing place of the '67 cable, which, we are glad to find, is in admirable working order.

The directors of the Indo-European Telegraph Company have issued a report showing most satisfactory progress throughout the great length of their line, and there is every hope of this means of communicating with India being completed by the end of the year. The submarine cable for the Black Sea is in course of manufacture, and will probably be submerged in June or July next.

M. Geissler, of Bonn, so well known for the electric fluorescent vacuum tubes, has lately succeeded in making tubes so that they become luminous by simple friction. A straight tube is formed into a spiral, and placed within a larger tube, to which it is united, and a vacuum is made in the inner tube only. On rubbing the outer tube—the effect is greater by the use of a cat's skin as a rubber—the inner tube becomes luminous, and of a colour corresponding to the gas filling it. The tubes formerly used generally required a Ruhmkorff coil of some size te give any really good luminosity, but we learn that with the new kind of tube, some have been constructed sufficiently large to illumine places totally obscure.

siderable reductions in the tariff have taken place, and, as is usual in such cases, a very large increase in business has been the consequence; so much so, niat, of Paris, in which they produced so great a hydrofluoric acid. Many of our readers who

vacuum that the electric spark could not pass. M.C. Schultz has lately been experimenting on this subject, and the results of his experiments go further. He states that the passage of a spark across rarefied air depends upon the tension of the spark. For instance, he established a vacuum in a Goissler tube, by means of a Geissler pump, so great, that a current from a Ruhmkorff coil would not pass, but by increasing the intensity of the primary current, the secondary current reappeared in the tube. A further vacuum was obtained so great, that the secondary current and its effect disappeared. This vacuum was, however, surmounted by sparks from a Holtz machine.

Some recent experiments upon magnetism have been communicated to the French Academy by M. Tréves. As there is an intimate relation between electricity and magnetism, and as electromagnetism was made use of in the experiment, we mention it for the information of our electrical readers, the object of the experiment being to see whether magnetism had any effect upon the cast-ing of iron. Two small moulds were made for the receiving of equal quantities of precisely similar molten iron, but under different conditions; the one was placed so as to be entirely removed from any magnetic influence, whilst the other was placed in a strong magnetic fluid; in fact, in the axis of a powerful electro-magnet, actuated by twelve Bunsen's elements. The moulds were filled with the molten liquid, and the electro-magnet exerted its influence, on the cooling of the metals; the two moulds were broken up, and on a careful analysis by a competent person, no difference in their crystallization was perceived, but an important fact was observed in the experiment, that a powerful magnetization of the casting was indubitably observed from its liquid state to its cool condition. After its thoroughly cooling, and had become solid, this magnetism remained, but in a less powerful condition; it was then a feeble magnet, but undoubtedly a magnet possessing two poles. It has been proved, years ago, that a magnet subjected to great temperature will lose its magnetism; but the present experiment would show that iron would remain magnetic at all temperatures, so long as the exciting cause continues. In 1865, M. Fave tried a somewhat analogous experiment; he dissolved in acid some soft iron, and coated it by galvanoplastic method, in a fine layer, on the surface of a plate of copper, and magnetized it. He proved that by applying heat to the iron (chemically pure), so great as to almost fuse the copper, that the coercitive force was so great, that the magnetism still remained, and remains up to the present.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

A CHEAP NICOL'S PRISM—PROCESS FOR COPTING OLD AND BARELY LEGIBLE WRITING—ANHYDROUS HYDROFLUORIC ACID—CEMENT FOR RETAINING VERY VOLATILE LIQUIDS,

THE Nicol's prisms, which our readers will have seen mentioned so often in the recent papers of Professor Tyndall, are expensive to obtain of any size. They are made of a crystal of calcspar, cut across diagonally, the two sections being afterwards joined together by means of Canada balsam. It has recently been discovered that a prism, possessing the same optical properties, may be made by constructing a vessel of glass, and inserting a thin plate of calc-spar across the diagonal, the vessel being filled up with bisulphide of carbon. If this be so, Nicol's prisms of considerable size may be made cheaply, since blocks of calc-spar of considerable size are often met with.

M. Niepce St. Victor gives a process for copying very old writings, which may be useful, if successful. Ordinary copying paper is to be used, but, instead of mere water, it is to be wetted with a thin solution of glucose or honey. On coming out of the press, the paper is to be exposed to strong ammonia, which, it is said, will bring out clearly writing which is barely visible.

Mr. Gore, who has achieved a great reputation as an investigator of the chemical properties of substances, under conditions not obtainable by ordinary students, has now taken in hand a body whose extraordinary properties render it an extremely difficult matter to deal with. We mean hydrofluoric acid. Many of our readers who

employ the strongest acid they can procure for technical purposes, will easily understand the difficulties and risks Mr. Gore must have undergone in procuring and ascertaining the chemical properties of the pure anhydrous acid, which he correctly describes as a highly dangerous subcorrectly describes as a highly dangerous atto-stance, requiring the most extreme care in its manipulation. It was obtained by heating the double fluoride of hydrogen and potassium in a platinum vessel, and nearly all the experiments with it were made while the vessels containing it were immersed in a freezing mixture of ice and crystallized chloride of calcium. Only under such conditions could experiments be made with safety to the air passages and eyesight of the operator. At 60deg. Fah., anhydrous fluoric acid is a colourless very mobile liquid. It is much more volatile than ether, and boils at 67deg. Fah. Whe specific gravity is 0.9879 at 55deg. Fah., water being 1,000deg. at the same temperature. When perfectly dry, it has no action on glass, and the dry gaseous acid was kept in glass vessels for several weeks without rendering them in the least degree dim. We may sum up very briefly the general chemical properties of the acid. It has scarcely any action on the noble metals and metalloids. Sodium and potassium behaved with it much the same as with water. Most salts were decomposed by its action, and most organic bodies, except fats, were dissolved by it. As regards the chemical constitution of the acid, Mr. Gore has determined that, to form it, one volume of hydrogen combines with one volume of fluorine without condensation, and in that respect it is allied to hydrochloric soid. The above is a short abstract of a most valuable contribution to science. Mr. Gore's next success, we hope, will be the isolation of the element fluorine, a body which, notwithstanding some assertions to the contrary, we believe has never been obtained in a separate

Chemists and others know well the difficulty of keeping very volatile liquids. Bottles of ether for example, are shipped for India, and when they arrive are found to be more than half empty. The chemist sometimes puts a bottle of benzole or bisul-phide of carbon on his shelves, and when he next requires it, he finds the bottle empty and dry. The remedy with exporters is a luting of melted sulphur, which is difficult to apply and hard to remove. A new cement, therefore, which is easily prepared and applied, and which is said to prevent the escape of the most volatile liquids, will be useful information to many. It is composed simply of very finely ground litharge and concentrated glycerine, and is merely painted around the cork or stopper. It quickly dries, and becomes extremely hard, but can be easily scraped of with a brite and the cork or stopper. off with a knife, when it is necessary to open the

# PARLIAMENTARY NOTES.

PARLIAMENT will doubtless have a busy time of it with matters more social than scientific in their character. Still, there are always questions arising which are of interest to our readers, and which are consistent with the matters discussed in our columns. These, then, in pursuance of our usual custom, we shall place before our readers, as they arise in either of the Houses. We may first note one or two things which came before the House of Commons yesterday week, when Mr. Dodson asked the House to agree to the following resolutions, the object of which was to facilitate the carrying out of the Railways Regulation Act of last session:-" That every railway bill promoted by an incorporated company and originating in this house shall, after having been read a first time, be referred to the examiner of petitions for private bills, who shall inquire and report as to compliance with the provisions of the Act 31st and 32nd Vict., c. 119, s. 35. The examiner shall give at least two clear days' notice in the Private Bill Office of the day appointed for such examination, and standing orders 76, 77, and 220 shall be applicable to any memorials com-plaining of non-compliance with such provisions. That in the case of such bills the time limited by standing order 191, between the first and second reading, shall be extended to, but shall in no case exceed, fourteen days." These resolutions he pro-posed to supplement by a further one, providing that in the case of a meeting of a railway company that all other places, if his place were not adopted,

being followed by a poll, all the documents relat-ing to it should be deposited in the Private Bill Office. The resolutions were agreed to.

Lord GARLIES asked the President of the Board of Trade whether it was intended to discontinue the light in Portpatrick Lighthouse; and if such change was intended, to state the reasons for its discontinuance.

Mr. BRIGHT said it was intended on the part of the Government to discontinue the harbour of Portpatrick, and also the light, as it was considered that that light was of no use to passing ships, and merely served harbour purposes. But of and merely served harbour purposes. But of course if it could be shown that the light was of use to passing vessels it would be allowed to remain. The information at present before the Board of Trade was that the light would not be necessary, and that the harbour ought consequently to be discontinued.

Mr. White gave notice that on going into committee of supply on the army estimates he should move the following resolution:—"That in order to promote greater economy and efficiency, the departments of the Horse Guards and the War Office should be placed under the control of one responsible minister."

On Monday Sir J. HAY gave notice that he would, on Friday next (to-day) call the attention of the House to the rule of the road at sea, and that he would put a question to the right hon. gentleman the President of the Board of Trade upon the subject. We hope something definite

will be settled upon this point.

At the same sitting Mr. CANDLISH asked the President of the Board of Trade if he expected to be able this session to bring in a bill to consolidate and amend the laws affecting our mercantile

marine.

Mr. Bright said it was the intention of the Board of Trade to introduce such a bill. The late Government had taken some steps to put the bill into shape, and it was at present in the hands of the draftsman. It was a bill which would contain an almost appalling number of clauses, and was one which dealt with a subject of great difficulty. When it was in a sufficiently advanced shape, it was the intention of the Board of Trade to consult gentlemen interested in the question, so as to gentiemen interested in the question, so as to make it in some degree complete before it was brought under the notice of the House. The measure would be kild on the table of the House in the course of the session, but he should be very sanguine indeed if he were to hope that it would pass during the present year.
On Tuesday Mr. J. Howard asked the Secre-

tary of State for the Home Department whether, considering the evils made public by the Report of the Rivers' Commission, it was the intention of the Government to introduce, during the present session, any measure for the prevention of the pollution of rivers and watercourses.

Mr. Bruce said that the important commission presided over by Sir William Denison were now examining the principal manufacturing districts in the Mersey and the Ribble, and that they intended to pursue their inquiries still further. He could not say when their report would be presented, but he hoped that it would lay down principles which would enable the House to legislate upon the subject without causing any great injury to our manufacturing interests.

Mr. BOURKE asked the President of the Board of Trade whether it was the intention of Her Majesty's Government to propose to carry out any of the recommendations which were made by the Royal Commissioners in the year 1859, on the subject of life harbours and harbours of refuge.

Mr. Bright said that the committee had made two principal suggestions; one of them, the Board of Trade and successive Governments had refused to adopt, while the second had been ever since in course of adoption. He would only say that was advanced constantly by the Public Works Loan Commissioners at a low rate of interest—a rate varying from 3½ to 3½ per cent.—to all places where there were persons who thought that the construction of a harbour was desirable, and who were willing to give security for the money so advanced. The Board of Trade was perfectly assured that if the first suggestion of the commissioners were adopted, it would lead to an almost unlimited expenditure of the public money. Any one who wished to have his mind satisfied upon that subject had only to turn to the evidence taken before the commissioners, where he would find that the evidence always went to the conclusion that the witness's own place was not

must be of no use whatever. The consequence was, that the course which the Board of Trade had hitherto pursued was the course which it would pursue for the future.

Lord Elono moved for the appointment of a committee to inquire into the roadway and viaduet proposed to be made on the Thames Embankment from Hungerford Bridge to Wellington-street, Strand, and whether the site might not be more advantageously occupied by some public building; also, to inquire whether any, and if so, what controlling power over public works in the metropolis was vested in and exercised by any Government Department.
Mr. Tire stated that the Metropolitan Board had

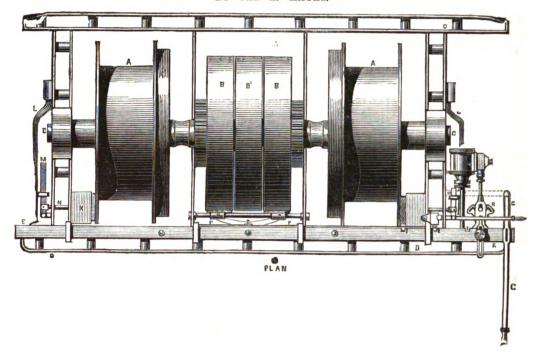

no feeling whatever in the matter, except to provide for the public benefit. It was no project of theirs, but at the same time he believed it had been much misunderstood. The simple question was the road between Westminster Bridge and Blackfriars was exactly a mile, and it was a pity that such a road should run parallel with Fleetstreet and the Strand without any lateral communication between them. However, if the committee took the responsibility of stopping this viaduct, and saving the expenditure of £230,000, it would rid the Metropolitan Board of an enormous difficulty. The only extent of viaduct that was proposed was to be 270 feet long, and the having of an arched way was forced upon the Board of Works by the Government. The object in having arches was to avoid interference with two graveyards which contained the remains of some very illustrious persons. If the committee could show how there could be a better communication, or how they could do without a lateral approach to the embankment, the board would have nothing more to say on the matter. As to the second part of the motion, it was formerly thought that the Chief Commissioner of Works was the proper authority to act. There had been very great improvements effected in London of late years, but it was a mistake to say that they had been paid for out of the rates; because the source of the revenue was the coal tax, of which the Board of Works took ninepence, and the City threepence. The motion was agreed to.

## THE METEOROLOGICAL SOCIETY.

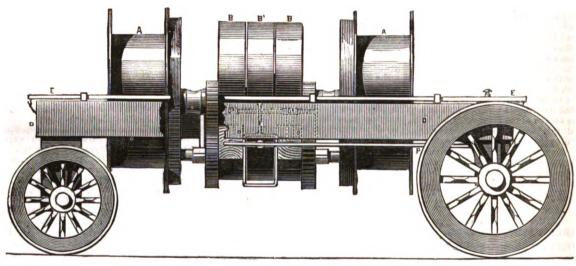

MEETING of this Society was held on the A 17th inst., at 7 p.m., at the Institute of Civil Engineers, James Glaisher, Esq., F.R.S., president, in the chair. Five gentlemen were balloted for and elected fellows of the Society. A paper was read, by C. O. F. Cator, Esq., which described his anemometer, as newly arranged with spiral apparatus, and gave an account of its registrations from September 11, 1868, to February 11, 1869. The discussion which followed turned rather upon the remarkable storm which passed up the English Channel on the 12th inst. than on the gales em-braced in the period. Incidentally, Colonel Strange raised the question of the relative value of velocity and pressure anemometers, whereupon an animated, if not angry, discussion took place as to the best method for converting velocity valves into pressure equivalents, et vice versa. Another paper was read, by C. Meldrum, Esq., of the Mauritius Meteorological Society, "On the Connection between the Rotation of the Wind in the South Indian Ocean and the Relative Positions of the Polar and Equatorial Currents." The author contended that in the South Indian Ocean wind gyrations occur in the direction of movement of watch hands, and also in the reverse direction. The object seemed to be to prove that the former, which are the normal gyrations, are frequently attended by gales and hurricanes, the winds circulating about an area of low atmospheric pressure; whilst the latter gyra-tions occur about areas of high pressure, and the winds are light. All this has been known for a long time, and has been well written upon by Buchan and others. But Mr. Meldrum seems to contend that these systems of circulation have always co-existence; the one being a necessary accompaniment of the other, and it only requires simultaneous observation over an extensive region to detect them. Dr. Mann remarked that at Natal the gyrations of the atmosphere, if, indeed, any occur, must take place in a vertical and not in a horizontal direction, for he had sought for evidence from the direction of the winds of that country from the direction of the winds of that country without success. There was but little further dis-cussion, probably because no one was clear upon the subject. This much, however, seems clear, that, in meteorology, as in other matters, old facts are continually being brought forward as new discoveries.

# PLOUGHING WINDLASS.

BY MR. E. HAYES.

SIDE ELEVATION

# HAYES' STEAM PLOUGH TACKLE.

To sa matter of history that we are indebted for the introduction of the steam plough principally to the labours of farmers who possessed some knowledge of mechanical science, and to engineers in a comparatively small way of business. Among these latter, Mr. E. Hayes, of Watling Works, Stoney Stratford, as far back as 1859, did much to introduce the steam plough into Buckinghamshire. introduce the steam plough into Buckinghamshire. He adopted the roundabout system in conjunction with a windlass distinct from the engine. This windlass he improved upon from time to time until it was very highly spoken of in 1862, when it was exhibited. Since that period, however, the inventor has turned his attention principally to a different branch of mechanical engineering, and, until very recently, although he continued to make ploughing tackle to order, he took no steps to introduce his system properly. Mr. Hayes, being known in Buckinghamshire as a maker of ploughing tackle, has found it worth his while to resort once more to its manufacture on an extended scale, and has recently effected years considerable insurance. recently effected very considerable improvements in his windlass, which entitle it to rank as one of the most ingenious combinations of mechanism in

This tackle consists of a portable engine—not self-propelling—of 10-horse power, a windlass, which we illustrate, and a set of anchors, wire rope, porters, &c. The engine has a single cylinder and a large boiler and firebox, but the windlass is the principal feature elaiming our attention. is the principal feature claiming our attention.

Mr. Hayes, knowing by experience that much time is lost at the headlands in stopping and starting the engine, or engines, where two are used, especially in foggy weather, when it is not easy to make signals, turned his attention to devising a system according to which the engine is never stopped while the tackle is at work, the delay at the headlands reduced to a minimum, and the control of the implement placed in the hands not only of the engine driver, but of the anchor man, at each headland, so that overrunning is impossible. the will of either anchor man, indeed, no matter how far removed from the engine, the implement can be stopped dead in about one second, certainly before it can traverse the distance of one foot. The engine is placed in one corner of the field to be ploughed or cultivated, with the windlass behind ploughed or cultivated, with the windlass behind it; the rope is then led round anchored pulleys, the only peculiarity being in the mode of anchor-ing at each headland the pulleys, which require to be moved at each bout. The movement is effected by the use of two plain claw anchors, to which the pulley is secured by double chains, so that it is placed at the apex of each triangle, and each anchor is lifted alternately to double the distance shifted by the implement at the end of each bout. A considerable saving of time is effected by this arrangement, but we have not space to describe it in detail.

The windlass consists essentially of two drums, on each of which the rope is wound alternately while it is payed off from the other. The drums are driven alternately from the engine by a belt

shifted from one pulley to the other. shifted from one pulley to the other. The drums A A on which the ropes are wound, the two pulleys B B which drive them, and the loose pulley B¹ in between, all revolve on the same axle C, this being a strong wrought-iron shaft, secured to a frame D D made of wrought-iron plates on the girder principle, and the whole mounted on feur wood wheels. This machine is so constructed that its centre of gravity shall fall low, thus preventing the wire ropes and strap from pulling the apparathe wire ropes and strap from pulling the apparatus out of its position. On one side of the frame is a flat bar of wrought-iron E, in the centre frame is a flat bar of wrought-iron E, in the centre of which is fixed the strap guide F. At each extremity of this bar is attached a spiral spring, connected to the frame of the windlass, and so set as to keep the strap on the loose pulley. When as to keep the strap on the loose pulley. When the strap requires moving to either of the driving pulleys, the bar E is moved by a lever G at one end-thus distending one of the spiral springs and is held in its place by a trigger or bolt H, which catches in one of three equi-distant notches I I I in the bar, to keep the strap guide opposite either of the pulleys required. When working, either of the pulleys required. When werking, one drum is, as we have said, winding and drawing the implement, which, in its turn, uncoils the loose rope from the other drum. Now, the occasional variations in the speed at which the implement travels cause great changes in the velocity of the uncoiling drum, and it would often uncoil the rope too fast running by its own momentum after a jerk. To prevent this, check brakes K K are affixed, one of which presses on the uncoiling drum by means of flat carriage springs L L. The

pressure of these springs can be regulated by their pressing on levers M M, instead of directly on to the brake spindles N N. As the brake is only required on the unwinding drum there is a short chain affixed to the end of the guide bar and the springs L L, so that when the bar is moved to give motion to either of the drums it takes the brake off at the same time. The engine driver or man in charge puts as little check as possible on the drum when at work, and this brake is not sufficient to arrest the uncoiling drum suddenly, and prevent coils of rope from running out should the implement require to stop in an instant. To prevent this in most other windlasses a man stands to put a brake on, but in this a far more effective system is adopted. Opposite each of the driving pulleys is a wooden brake O O, secured to ironwork O 1. This is connected by means of a long lever P to a piston rod working from a small cylinder Q at the end of the frame, the side valve of which is worked by a cam R connected with the strap bar, and made so that the bar in moving opens the slide valve or closes it altogether, putting on the pressure when the strap is on the loose pulley, and taking it off when it is moved to either of the driving pulleys. The pressure is obtained through a §in. tube, of canvas and india rubber, from the boiler; water is used, and at the steam pressure of the boiler. The piston moves about §in., and the brakes about §in., and puts on and takes off without noise, or attention from any one,

we have already stated that there are three notches I I I, cut into the bar, into which a small bolt or trigger H springs, to keep the bar in its position, and also that when the bar is moved to throw the strap on a driving pulley is moved against two springs, one spiral, and one flat carriage spring. It will be seen, therefore, that when at work, if the trigger be drawn from the notch, the bar will be forced into its central position by the springs, and will put the strap on the loose pulley, the water brake at the same moment being applied. Attached to this trigger or bolt are two small cords, and these are taken across the field to the anchor men. By pulling these cords they can stop the implement at the headland or any part of the field, thus enabling them to work in fogs, hilly fields, or by moonlight. The same cords ring a bell on the windlass as a signal to the driver to move the strap to the driving pulley again. The driving pulleys are connected to the drums by means of internal wheel-gear, the sliding bar E forms the key, so to speak, to the operation of the entire machine. Left to itself it would always put the strap on the loose pulley, and as it is moved to one side or other so the strap is applied to their proper wheels. The engineer attends the windlass, his duties as regards it simply consisting in shifting the strap from one pulley to the other as the plough reaches such headland. Mr. Haves apparatus has now been at work for some time on arious farms with good results. We believe Mr. Hayes intends working his machinery on a farm near his works about the middle of March next, in order to give those interested in the question of steam cultivation an opportunity of judging of its merits.

THE "France" says :- We have a resuscitation of sedan chairs. Four of them have been seen in the old faubourg. One was observed at the hotel of the de la Rochefoucault-Bisaccia, a third of the Princess de la Tremouille, and the fourth of the Marquise de Fincenes. Up to this time the chairs in question have only been used for going to church and for short morning visits. A special toilet has been invented for this sort of conveyance, consisting of a black mantilla trimmed with guipure, and the cos-tume is called a "sortie d'eglise."

THE MANUFACTURE OF WATCHES AND CLOCKS.

THE MANUFACTURE OF WATCHES AND CLOCKS.

—A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 69, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices, and no one should make a purchase without visiting the above establishments or consultwith their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, who holds the appointment to the Prince of Wales, sends the appointment to the Prince of Wales, sends this pamphlet to any address on receipt of two postage stamps, and we cannot too strongly recommend it to the notice of the intending purchaser.—| ADVT. | ON A NEW FORM OF PERMANENT MAGNET

BY Mr. F. A. PAGET.\*

WITHOUT any distinctly given reason, it is taken for granted in all works on magnetism, and in all the practical applications of mechanism, that it is impossible to magnetize a plate except in the direction of its length.

Michell, in his "Treatise on Artificial Magnets, gives a determinate proportion, but without stating any reason, between the length and the weight of magnets. A magnet, for instance, 2in. long, should weigh one-tenth of a pound. Cavallo recommends a width of one-tenth; Fuss one-sixth; Musschenbroeck and, later, Coulomb, one twenty-fourth of the length. In all these cases it is assumed that the direction of the poles must be parallel with the longest dimensions of the solid bar or plate to be magnetized, and that it is impossible to regularly magnetize a square plate, and still less an oblong plate, in a direction transverse to its major axis. That this is correct with a solid continuous plate can be easily proved by experiment, and it is well known to instrument makers that it is impossible to permanently magnetize a square steel plate. No doubt such magnetize a square steel plate. No doubt such results would greatly vary with the constitution and state of the steel employed, the relations of its different dimensions, the mode of magnetization adopted; but the only experiment bearing on the question that I can discover, after much research in scientific works, is that of De la Borne, † who found, on magnetizing steel discs, that as long as found, on magnetizing steel dises, that as long as they were whole they showed no polarity, and that their polarity only appeared when they were cut in two. Dr. Lamont, in a paper which first appeared in Poggendorfi's "Annalen" (Vol. CXIII.), and was communicated to the "Philosophical Magazine" for November, 1861, by the Astronomer Royal, investigated the question of "the most advantageous form of magnets," or that form in which "are united the greatest possible magnetic mounent with the smallest possible mass and the smallest possible moment of inertia." In all the forms he experimented upon the breadth was always less than one-third of the length, and generally about one-fifth, and he does not seem to contemplate the possibility of magnetizing a square plate, and still less an oblong plate, in a direction transverse to its greatest length. Now, I find that by cutting slits nearly up to the middle of a steel plate a square plate in one piece can with such slits be regularly magnetized, and by this means even an oblong square plate can be regularly magnetized, and with as many poles as may be required in a direction transverse to its greatest length.

I herewith beg to forward a square plate magnetized in this way. It is of watch-spring steel, 0.0075in, thick and  $\frac{2}{3}$ in,  $\times \frac{2}{3}$ in, it has four pairs of alth  $\frac{1}{3}$ in  $\times \frac{2}{3}$ in, it has four of slits lin. wide cut from its edges, leaving a central web  $\frac{1}{4}$ in. wide uniting the whole. On moving a small needle round this square plate it is seen to be regularly magnetized, and on sprinkling iron filings on the magnet, covered by a sheet of paper, they arrange themselves in lines, proving that the magnet really consists of a number of small regular similar magnets, arranged below each other in the same vertical plane. On suspending an oblong magnet of this kind, with its longer axis in the vertical plane. On suspending an oblong magnet of this the needles set themselves to the magnetic meridian; on suspending it flatwise, with its longer axis in the horizontal plane, the longer axis points east and west. As well as can be judged by subjecting them to slight shocks, the magnets are as permanently magnetized as if they were separate from each other. Only time can prove whether they will lose their magnetism. The important question as to what form is the best for retaining magnetism for a length of time is one which, as Lamont remarks, no one has yet investigated.

Though I have not yet been enabled to try to magnetize a parallelopipedon of steel after slotting it vertically and transversely into a number of bars, held together by a central web, I feel very confident that this could be done. The slots could be cut into the parallelopipedon or cube while in a soft state by a thin tool, worked to and fro in an ordinary engineer's slotting or shaping machine, and the whole magnetized in a powerful electric spiral, in the way described by Elias. Besides moving the spiral to and fro, as described by him, no doubt in order to overcome the resistance to induction, the cube while in the spiral could also be struck, in order to produce that mechanical

vibration which is so favourable to magnetization and demagnetization. By pointing the needles, or giving them the rhomboidal form, it is evident that, in spite of the poles being nearer (as is well ascertained to be the case in needles of that shape), the ratio of the magnetic moment to the moment of inertia is still higher than in the assemblage of oblong needles. Though, for various reasons, the rhomboid set on its edge is scarcely ever used in practice, an easy calculation shows that it is the most perfect form for a movable magnet. It seems only to have been tried when lying flat.

#### ROYAL POLYTECHNIC INSTITUTION.

O<sup>N</sup> Saturday last, the Annual Meeting of the above popular Institution was held at the establishment in Regent Street. The chair was occupied by the Rev. J. B. Owen, and Professor Pepper, as honorary director and manager, read his report, which was of a most satisfactory character. Notwithstanding the heat of the summer weather, and the large increase of out-door attractions, the money taken at the doors during a series of several years was, as compared with the amount taken that year, not the lowest. Although, taking the year through, there had been a reduction in the amount of receipts, as compared with the previous year, of £1,000, there had been a corresponding year, of £1,000, there had been a corresponding reduction in expenditure. Amongst the new features which had attracted great public attention during the half-year had been the new electric organ, by Messes. Bryceson, the lectures on the solar eclipse, and the earthquakes in Mexico, with pictorial illustrations; whilst Mr. Tobin, in conjunction with himself, had produced some new spectral illusions of an astounding character; and the mammoth electric magnetic coil, which had been alluded to in previous reports, was now just completed, and there was every reason to believe that it would produce great and important improvements of a scientific character.

The Rev. C. Mackenzie reported that the educational department had been also successful. prizes were distributed to the successful candidates, in November last, by the Venerable Archdeacon of Nottingham. The winner of the late Prince Consort's prize was Robert Kingston, who was a

gardener, earning but 15s. a week.
From the Rev. Chairman's remarks we are glad to be able to state that the results of the past have been satisfactory in a general sense, although it appears that the takings at the doors showed a slight decrease. The various exhibitions, such as the Mysterious Hand, the Electric Organ, the optical illusion, called "The Spectre Barber" continue to prove as interesting and as attractive as anything to be seen elsewhere. We congratulate the shareholders that, notwithstanding the drawbacks which from a variety of circumstances have had to be encountered, the institution is still one of those which from its popularity continues to be a success. The receipts of the half-year from visitors, at 1s., wore £3,134 18s. 6d.; workmen and children at 6d. £501 10s. 6d.; and other items, such as reserved seats. &c., have brought the aggre-gate amount up to £4,576 19s. 6J. Although con-siderable expenses have been incurred, the profits allow of the payment of a dividend at the rate of  $3\frac{1}{2}$  per cent. for the half-year, making, with that already paid,  $8\frac{1}{2}$  per cent. per annum, a condition of things which must be highly gratifying to both the executive and the shareholders.

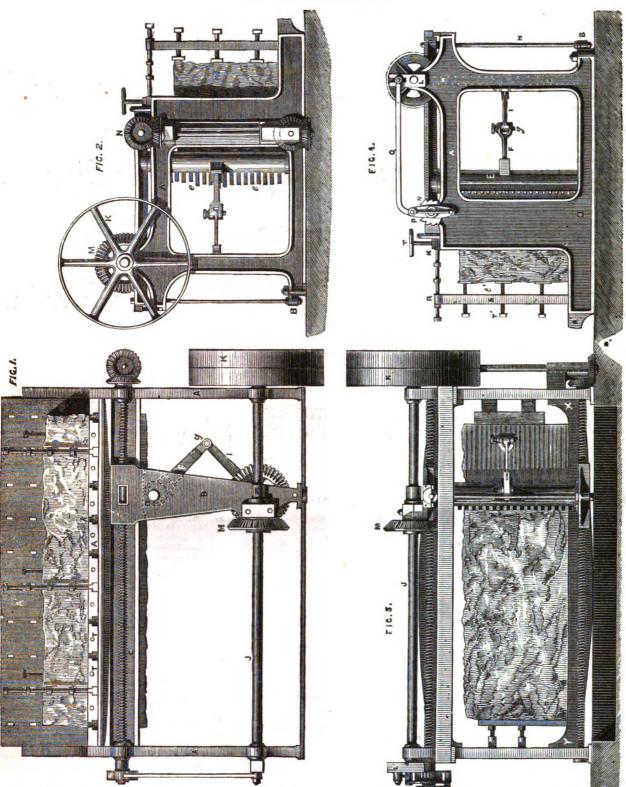

# STONE DRESSING BY MACHINERY.

NY mechanical process which tends to cheapen the labour cost upon materials for building ourposes is always welcome in a double sense. facilitates the construction of buildings of superior character for a comparatively moderate cost, thus proving a source of gain to owners of property, and it adds to the appearance of our thoroughfares, and thus becomes a national boon. In the present instance we have to notice a progressive step in the mechanical dressing of stone, which has been made by Mr. J. E. Holmes, of Chester. This machine has been introduced by the patentee with a view to facilitate the dressing of stones, especially those of the harder and more enduring class. This enables those engaged either in the production or use of stone to avail themselves of steam or water power for the performance of the more laborious part of their work. In the construction of the machine Mr. Holmes has applied the working tools to the surface of the stone in the same direction, and with the same effect as the chisel in the hands of the skilled workman. That this arrangement has been successful is evidenced by

<sup>·</sup> Communicated by the author to the "Philosophical Magazine."
† Pogg. "Ann." vol. lxxil. p. 26.

# STONE-DRESSING MACHINERY.

BY MR. J. E. HOLMES.

the satisfaction the machine has given wherever it has been introduced. We examined this machine on Wednesday last at the Salisbury Wharf, Strand, where Mr. Holmes has one on view, and found its action to be very perfect. On plain surfaces the quality of the work is equal to the best that can be produced by hand labour, while many of the mouldings, angles, and bevels required in ornamental work can be executed with facility. With these machines the quantity of stones dressed depends more upon the convenient arrangements for handling and turning over the stones, than upon the actual time of cutting. The forward feed over the surface of even the largest stones will be from 18 to 24 inches per minute; if well quarried and scabbled, two or three cuts will finish a face of 15 to 20 superficial feet in as many minutes. On smaller stones of course the proportionate quantity dressed would not be so great. Beds and joints

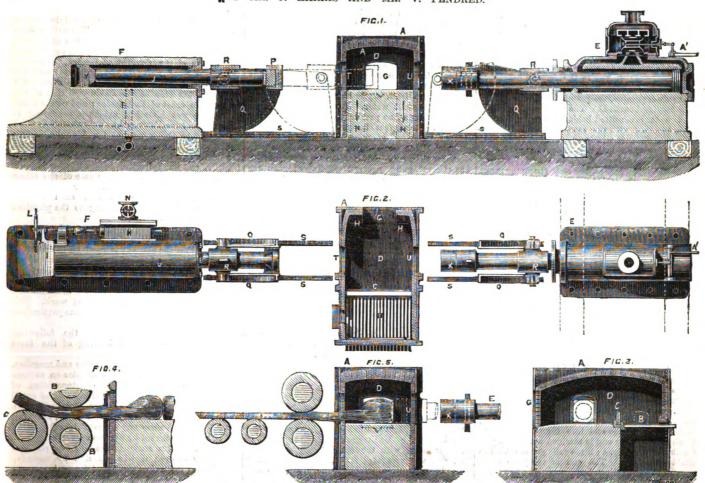

require but two cuts, if well shaped, and by using punches or grooving points, a regular matching or dovetailing of the courses may be obtained.

The general character of the machine and its mode of operation will be readily understood from our engravings, for which, and the annexed description, we are indebted to the "Mining Journal." We may premise that the machine shown in the engraving will dress a stone 7 ft. by 2 ft. 9 in. A A is the main framing, which comprises the bed-plate, A¹, on which the block of stone to be cut is fixed. B B are travelling arms, in which the cutter-stock or crosshead (fitted with chisels, picks, and tools) is mounted, and which arms and cutters are made to traverse the main frame, A A, from end to end alternately, or from left to right, and vice versa, by the screws, cc; dd are eccentric bearings, or plummer-blocks, in which the ends or journals of the cutter-stock or cross-head are centred. These bearings may be turned by a lever or levers, not shown in the engrav-

ings, and may be fixed in position by stop-bolts; e is the cutter-stock or cross-head, in which the picks, chisels, and tools are fixed. The picks or chisels are shown at ee. A lever, F, is fixed to the stock or cross-head for giving right and left hand cutting motions to the chisels or tools, as the case may be, this lever being coupled by the connecting-rod, I, to the crank of a cranked shaft, G, centred in the centre of the travelling arms, B, and turned by the mitre wheel, H. By taking out the pin, g, the connecting-rod, I, can be readily uncoupled, and the lever, F, turned so that it inclines in the opposite direction, for the purpose which we shall explain presently. J is the main shaft, having a driving-pulley, K, keyed on it at one end, and a slotted crank, L, also keyed at the other end. M is a second mitre wheel, mounted upon a short hollow shaft, m, which turns in a bearing provided on the head of one of the travelling arms, B. The main shaft, J, has a long groove cut in it to receive a tongue, or feather, in the hollow of the shaft m,

# APPARATUS FOR MANUFACTURING WROUGHT IRON AND STEEL.

BY MR. J. HARRIS AND MR. V. PENDRED.

which is thus turned by, and traverses on, the main shaft from end to end, as the arms B B are moved backwards and forwards by the screws C C. The heads of the arms B B are connected by the tie, or parallel bar, h. Bevel wheels, N, are keyed on to the ends of the screws C C, and are connected by a shaft carrying other bevel wheels, as shown. O is a ratchet wheel, fixed on the upper screw shaft at the opposite end to the bevel wheel N; whilst P, a lever centred upon the ratchet wheel O, and fitted with a double or reversing pawl, adjustable for turning the screws C C from left to right, or vice ve sa, according to the direction in which it is desired to work the cutter. A connecting-rod, or link, Q, gives a rocking motion to the lever P, by the revolutions of the slotted crank L, on the end of the main shaft. The crankpin of this crank works in a hollow screw clamp, and by varying the position of the crank-pin, the lever P can be made to turn the screws C C more or less at each revolution of the main shaft J, and thus regulate the feed. R, S and T are the clamps, screws, and cross bars by which the stone is secured in position while being dressed.

dressed.

In practice, the stone to be dressed is placed upon the bed-plate of the machine, with the side to be operated upon towards the cutters, and it is then fixed in position by the clamps and screws. The cutters having been previously moved to one end of the machine, and the cutter-head set to the required angle, the power is applied through the pulley to the main shaft, whereby the whole of the moving part of the machine will be set in motion. If the block be tolerably quarry-faced, the surface operated upon will be cut nearly true by the narrow chirsels at one traverse of the cutter-arms; and then by reversing the cutter-stock, so as to bring the broad chisels into play, the stone will be evenly tooled and finished on the back journey of the cutter-arms; by turning the block, the beds, faces, and joints may be dressed with truth and rapidity. By inclining the bed-plate or table more or less, any required angle may be given to the surfaces. Hence, when the machine is once set, the work produced by it upon any number of blocks will be perfectly uniform, causing their beds and faces, or the angle of their surfaces to each other, to be perfectly true one with another. Thus, the use of square bevels and templates, &c., and the loss of time for setting out and working marginal drafts, as when dressed by hand labour, may be avoided.

Where the stone requires a second or third rough chiselling before applying the broad tools, either the cutter-stocks can be made reversible, or the tools may be turned to clear the face, and the chisels run back. The machines can be made of almost any size, but Mr. Holmes considers it most convenient for ordinary purposes to make the cutter-stock give a cut 3ft. wide, with a traverse motion of 8ft., or so as to dress the surfaces of a block of any size up to 7ft. in length by 3ft. in width. For convenience of locomotion, the main frame may be provided with wheels, and, when necessary, a swing or travelling crane may be added to facilitate the operations of moving and turning the blocks of stone to and from and upon the bed-plate. We may add that these machines are now being manufactured by Messrs. Ormerod, Grierson and Co., of Manchester, and by Mr. B. Johnson, of Chester.

# IMPROVED METHOD OF MANUFACTUR-ING WROUGHT IRON AND STEEL.

DY the invention we are about to describe, and which is illustrated in the accompanying engravings, some important improvements are effected in the manufacture of wrought iron and steel, whereby the production of homogeneous masses of iron or steel may be accomplished with ease and certainty. This invention has recently been patented by Mr. John Harris, of the Harefield Iron Works, Middlesex, and Mr. Vaughan Pendred, of Crohill Villa, Milton-road, Dulwich. By the aid of this process, masses of iron or steel may be produced of sufficient size to form a girder, rail, shaft, armour-plate, &c., which will be homogeneous throughout, in so far that they will be without any weld, in the ordinary sense of the term. Some years since, the welding of two or more puddled balls into one, under a steam hammer, was practised in Wales, and, by this means, large masses were produced, but the process was not satisfactory, because the surfaces of the balls became oxidized, and good union could not always be secured between them in consequence. Puddled balls are now welded in the same way, both at Consett Iron Works, Durham, and on the continent of Europe, but the process is, in both cases, open to the objec-

tion we have just pointed out. Now, by welding the puddled balls together in a furnace, according to the present invention, a perfect union is secured, because the iron at the time of welding is surrounded by a deoxidizing or neutral flame, caused to be present in the forging hearth by regulating the damper. The formation of scale is thus effectually prevented on the faces to be united; the iron or steel, too, being maintained at a high temperature, the cinder or slag is kept fluid or lively, and may be the better expelled. Another advantage is that the cost of producing rails, armour-plates, &c., will thus be much reduced, because a mass of homogeneous iron or steel may be made at once of sufficient size to form a rail, armour-plate, or shaft, and the process of reheating, cutting, and piling, may therefore he dispensed with.

acc., will thus be much reduced, because a mass of sufficient size to form a rail, armour-plate, or shaft, and the process of reheating, cutting, and piling, may, therefore, be dispensed with.

In our engraving, A, figs. 1, 2, 3, 4, and 5 is the welding furnace shown in end section in fig. 1, in plan at fig. 2, and in longitudinal section at fig. 3; B is the grate; C, the bridge; and D, the forging hearth or chamber; E, figs. 1, 2, and 5, is the steam hammer; and F, figs. 1 and 2, is the hydraulic anvil. The products of combustion are led away from the forging hearth to a suitable stack by two flues, opening into the hearth near the charging opening G, and marked by the dotted lines H H, fig. 2, which descend into a horizontal flue. The hydraulic anvil consists of a heavy casting I, figs. 1 and 2, in the upper part of which is a cylindrical cavity, within which the ram J works; this ram is double-acting. Water is admitted to either end of the cylindrical cavity by a common slide valve, contained in the box K, and actuated by the hand wheel L and the screw M, fig. 2. The water is introduced under pressure obtained by an accumulator, or otherwise, into the box K, through the stop valve N, and is withdrawn from the ends of the cylinder by the pipe O, fig. 1. The ram J is made of such length that it may be thrustinto the middle of the width of the furnace, and it is made with a dovetail slot in the end to enable a head or tup of any required form to be secured to it, as shown at P, in figs. 1 and 2. Q Q are two arcs or segments of wrought or east iron pivoting on the crosshead R; these arcs support the weight of the ram, rolling on the rails S S. When the ram

is thrust forward as far as it will go, the arcs assume the position shown by the dotted lines in fig. 1. The ram enters through the opening T, figs. 1 and 2. G, figs. 1 and 2, is the charging door through which the puddled balls to be welded are introduced.

E, figs. 1, 2, and 5, is the steam hammer, the ram or tup of which is supported by two arcs Q Q, a crosshead R, and rails S S, figs. 1 and 2. hammer is in other respects not different from ordinary hammers. The head or tup X of this hammer is made so that it can easily be replaced when worn out; it enters the forging hearth D through the opening U, figs. 1, 2, 3, and 5. In using this apparatus, the puddled balls are placed in the forging hearth D. The door closing T is raised water is admitted behind the ram piston V, which, together with the ram, is pushed forward to a proper distance within the furnace, or until it touches the puddled ball. The door closing U is then opened, and the lever A 1, figs. 1 and 2, being actuated by an attendant, the steam hammer is put in motion, and the puddled ball resting against the anvil ram J, is slightly flattened. Another ball is then placed in contact with the first, and welded to it by blows from the steam hammer, and the process is continued as quickly as the balls can be properly with suitable tools, through the charging hole G. As the mass in Directory ram J is caused to recede by an attendant, actuating the hand wheel L. When the mass has reached the required size, J is withdrawn altogether, and the mass is pushed out through T on to a trolly and is removed to be dealt with by rolling, hammering, &c., being still at a welding heat. If found desirable, a stream of water may be made to circulate through those portions of the anvil and steam hammer exposed to a great heat, in order to keep them cool

In some cases, the anvil I J is dispensed with. rolls being substituted in its stead. This modifica-tion is shown in figs. 4 and 5. In fig. 4, the manufacture of a curved armour-plate is illustrated. In carrying out this portion of the invention, a piece of armour-plate, or other heavy plate, is introduced at one end into the foreing hearth D, while the other end is retained between a pair of rolls B<sup>1</sup> B<sup>1</sup>, fig. 4; these rolls are mounted in suitable housings. The end of the plate being brought to a welding heat, puddled balls are welded against the end by the steam hammer. After a sufficient number of balls are thus attached to the plate and to each other, the rolls are put in motion, and the plate withdrawn and rolled back-wards and forwards, the rolls having a reverse motion until the proper thickness is attained. end of the plate is then restored to the welding furnace and more puddled balls welded to the It is then once more withdrawn, and the additional length of iron so secured is rolled down to the proper thickness. C is a roll so placed as to give the required curve to the plate. way, semicircular rings of solid iron may be made for turrets. Fig. 5 illustrates the manufacture of a flat armour-plate. In some cases, the rolls have a slow continuous motion in one direction, so that the slab of iron is withdrawn from the furnace at just the same rate that it is increased in length by the addition of puddled balls, and two or more sets of rolls may be worked in advance of each other in order to bring the plate to the proper thickness. In all cases, the rolls have water circulated through In our engraving, they are shown hollow and filled with water, but this arrangement may be varied to suit circumstances. In some cases, the inventors substitute for the steam hammer a second hydraulic anvil, and they then accomplish the welding together of the puddled balls by pressure instead of percussion. The two so-called anvils then act the part of hydraulic presses, between which the puddled balls are squeezed together.

LAGOONS AND MARSHES ON THE SHORES OF THE MEDITERRANEAN.

BY PROFESSOR ANSTED, F.R.S.

AT a meeting of the Institution of Civil Engineers, held February 16, 1869, Mr. C. H. Gregory, President, in the chair, the paper read was on the lagoons and marshes of certain parts of the shores of the Mediterranean.

The author commenced by alluding to the relations of physical geography and geology to engineering, and proceeded to describe the state of the Rhone, its delta and the tract called the Camargue. He remarked that the actual delta was limited to the west by the stream of the wide near the Golo, and 400 yards at the other end.

Vidourle, and to the east by the Cran: its extreme breadth being 40 miles, and its area 180,000 acres; and he noticed that while the main stream had gradually been shifting towards the east, the pseudo-deltaic formations subordinate to it had south. He then alluded to the condition of the Rhone current, and the evidence that the delta had advanced outwards towards the sea within the historic period by a distance measured by miles. The mode of formation of the delta was described as follows:-Sand, drifted by marine currents from the south-east from beyond the mouth of the Rhone, formed mounds or dunes, at places where fresh water running down from the land met the salt water. The dunes increased in number along a line parallel to the shore, till they formed an imperfect border to brackish-water lagoons. During summer, the dunes became connected, and in the rainy season breaches were caused by the sea. At length, a complete barrier was effected, and a nearly fresh-water lagoon was The same work was then repeated, and formed. the lagoon was filled up, more or less completely. in the course of time, by warping, so that a permanent addition was made to the land. The largest lagoon of the delta (that of Valcares) was next described. It covered 25,000 acres, and was protected by an artificial sand dyke, 161 miles completed in 1857. The other executed, with the exception of some locks and canals to keep open channels to the sea, were very

Details were next given of the great system of lagoons extending beyond the true delta of the Rhone to the Cape of Agde, a distance of nearly 40 miles, which the author believed to be of no great geological antiquity. Beyond the delta, the district consisted at first of the tertiary deposits, near Montpellier, then of the jurassic formations of the ridge of the Gardčole, and finally of the basaltic rocks, continued from Central France, and which terminated at the Cape of Agde.

lagoon of Mauguio, the first beyond the Vidourle, had an area of 8,000 acres; its greatest depth was 4ft. 7in. and the level of the water was below the Mediterranean in summer. communicated with the sea by only one opening, and was separated from it by a sandbank at 11 mile wide, gradually narrowing to 500 yards or 600 yards. Towards the land were extensive marshes, and all the villages around were very unhealthy. It received the drainage of about 78 square miles, by a number of streams, the longest of which was about 13 miles. This lagoon was nearly separated from the next (the lagoon of Perols) by a tongue of land, beyond which came the drainage of a stream (the Lez). The lagoon of Perols, and the next in order, that of Grec, covered about 3,300 acres, of which about 2,425 were under water, the rest being marsh. The maximum depth of water was only 33in. below the summer water level, which was 7in, below the Mediterranean. The marshes around were about 10in. above the water level. lagoons received little water from the land immediately around. They had been fed almost entirely from the drainage area of the Lez, now conducted by canals direct to the sea. The drainage area of the Lez was 125 square miles, but the effect of rain was rapid and considerable owing to the form of the ground, and the extremely heavy showers that sometimes fell. There were three lagoons between that of Grec and the great lagoon of Thau, the total water area being 11,280 acres. They received the drainage of about 33 square miles of country, and the physical conditions accounted for the lagoons. The lagoon of Thau covered 20,000 acres, its only natural outlet being at the extreme south. It received the drainage of about 120 square miles of The works projected for the improvecountry. ment of the sanitary condition of the coast, and the recovery of the marsh lands, were next alluded to, and were stated to be on the whole satisfactory.

Attention was then directed to the lagoons of the East Coast of Corsica. These were derived from the detritus brought down by the rivers from the mountains. The Golo was the chief river, and the lagoon of Biguglia the largest lagoon. It extended north of the Golo, its length being 73 miles, and average breadth for six miles 1,000 yards. Beyond this, to the north, was a narrow neck of water communicating with the sea. The total water area was 4,750 acres; the maximum depth was 4ft. 6in. and the mean depth 333 in. It was separated from the sea by a sand bank, 900 yards wide near the Golo, and 400 yards at the other end.

During storms, the waves washed over it at two points. The water was sometimes fresh, and sometimes salt. The drainage area supplying water to the lagoon was 70 square miles, but it was made up of three parts,-one between the Golo and the river Bevinco, the principal feeder,the next, the drainage area of the Bevinco,-and the other, a small space of ground supplying water to the neck beyond the Bevinco. The author then explained the history of the lagoon, and pointed out that by separating the district, and conducting the waters of the Bevinco to the sea, the condition of the larger part (about 4,000 acres) was not at all unfavourable for complete drainage. He compared the case of the Bevinco to that of the Lez, on the coast of Languedoc; and pointed out that there was historical evidence rendering it probable that the Bevinco had only recently added its waters to the lagoon of the Biguglia, owing to the gradual advance of the dunes that inclosed the latter; and that the coast was comparatively healthy, and was inhabited, before this event took place. He mentioned that the case of the other lagoons along the coast was similar generally to that of the Biguglia; but that each needed separate consideration, according to the physical geography of the district.

Rainfall statistics both of the coast of Languedoc and that of Corsica were then given, from which it appeared that the average rainfall on the coast of France, near the delta of the Rhone, was about 36in., and of the coast of Corsica not more than 24in. for the years of observation. The extremes were, however, very great, and the mean annual fall was of little value for practical work. The seasonal falls were also given, and some particulars

of heavy rain on both coasts.

The author concluded with the following summary of the practical bearing of the facts adduced:—

First. That the malarious lagoons and marshes, of which there were so many examples on various shores, were the result of the interception of waters coming off small tracts of land, or of small and torrential streams, by banks of drifted sand and mud, proceeding from larger rivers, carrying out to some distance large quantities of detritus which was distributed by marine currents.

Second. That a study of the existing physical geography of each district affected by malaria, combined with a knowledge of its geology, was sufficient to explain the conditions, and to determine the history of the operations that had terminated in the formation of the malarious marshes and lagoons.

Third. That the removal of malaria, whether

Third. That the removal of malaria, whether to be effected by complete drainage or by partial drainage, accompanied by the keeping certain lagoons in free communication with the sea, could only be hoped for by engineering operations, based on the special history of the case under consideration, as determined by a knowledge of the physical geography and geology of the district.

Fourth. That, in certain cases where small torrential streams had been kept back from the sea by the rapid accumulation of drifted sand, the drainage of the marshes and lagoons might be rendered comparatively easy by keeping open a permanent channel for such streams.

Fifth. That the principle of breaking up the drainage areas supplying water to the lagoons into smaller areas, each of which admitted of separate treatment, being suggested by the history of lagoons generally, was the principle which should be adopted in all cases where sanitary improvement was called for, and would generally be found advantageous in an economic sense.

ALAND'S INJECTOR FAN BLOWER, AND EXHAUSTER.

cently been effected by Mr. Aland in the construction of rotary blowing fans, by which their efficacy is much augmented, and their cost materially diminished. These desirable consequences have resulted from a close observation of the defects of existing contrivances of the kind, and a series of practical experiments for the purpose of obviating them. It is well known to ironfounders and others that the driving of fans at very high velocities absorbs considerable steam power, and that the operation is attended by a very unpleasant noise. In addition to these disadvantages, it has been conclusively demonstrated by the gentleman above named that much of the air "sucked," so to speak, into the casing of the old fans is again expelled through the "eyes," and, therefore, wasted. This is a fact which may be easily proved by placing the hand or a lighted

candle near the openings alluded to when the fan is at full speed. The blades in such instances are literally "beating the air," and losing nearly half the effect they should produce on the furnace. It was mainly with a view to economizing the power employed in propelling fans, and ensuring the complete utilization of the air set in motion by the blades, that Mr. Aland devoted his attention to the subject. It is satisfactory to be able to state that he has accomplished both these desiderata, and that if he has not annihilated the humming noise, which—if heard by Mr. Babbage, would make that gentleman more lenient to itinerant musicians—he has certainly minimized it. It will be some con-solation to those who possess old and noisy fans to be informed that at a very small cost, and in very

short time, they may have them modified and silenced on the patented principle of Mr. Aland. The main features of the alterations introduced may be briefly adverted to. They consist in the formation of lateral spaces between the sides of the fan and its outer easing, and the application of a ring of metal, inclining inwards, to the periphery of the inlet openings. The effect of this last-named arrangement is to direct a certain pressure from the discharge to the supply side, near the centre of the fan, and thus to intensify, as it were, the density of the air within the casing, and give the blades something more substantial to deal with than ordinary atmospheric molecules. It will be readily understood that by such a mode of procedure it becomes simply impossible for any portion of air that has once gained admission to the fan chamber to go in any direction but the right one, or do anything which is not desired. Leakage has thus been positively and completely obviated; the engine no longer does unnecessary duty, and, of course, not one pound of fuel is needlessly consumed under its boiler. Another advantage arising from the creation of a superior and uniformly preserved density of air within the fan chamber, is that "back lash," so destructive of ordinary fans, is entirely avoided. The blades impinge upon a steadily-resisting medium, and they as steadily overcome its inertia and make it "move on" in a constant stream to the furnace.

From personal inspection of the Aland fan we are enabled to speak in positive terms of its superiority over all others at present in use, and in the interest of our readers, therefore, its merits are now referred to. It is unknown to us whether or not the inventor has thought of introducing his fan to the notice of mine owners, and others con-cerned in the operations of "the world underground," but there can be no doubt of its value as an accessory to those operations. Whether used in sucking poisonous and deadly gases out of the galleries and workings of a coal pit on the exhaustive system, or in blowing fresh air down to dilute fire-damp, and render it non-explosive and innoxious, the Aland fan must prove—as we think—of the highest service.

In converting the fan into an exhauster, it would be simply necessary to connect the two inlet openings, by means of enclosed side pipes, with the chamber vessel or space to be exhausted. It remains to be said that in deciding upon the form of the blades of this contrivance, the inventor followed very closely such scientific theories as seemed very closely in regard to them, and that purples. most rational in regard to them, and that professional knowledge and actual experimentation have enabled him to reduce those theories to successful practice. The fan blades are curved laterally and vertically in a peculiar way, and in their action they "beget a smoothness" which is not attained to by those of a flat and rectangular shape. It would be improper to omit saying that the outer casing of the Aland fan is not flanged and belted casing of the Aland fan is not flanged and bolted together perpendicularly as is usual, but is formed in two halves, and united horizontally. The roof of the casing—if the term be admissible—is of cast iron, very thin and light, and of a not ungraceful shape. The contrivance is of a simple character, so far as details are concerned, the friction of parts being very slight, and choking at the sides scarcely possible under any circumstances.

# A NEW ANCHOR.

A NEW ANCHOR.

It is now upwards of fifty years since Mr. Pering first drew the attention of the British navy to the defective character of the old plan long shanked anchor, which was the only one then in use in the navy. Since that time many and various improvements and modifications have been suggested and made. The effort has been to make an anchor which shall be more effective, and at the same time less cumbersome than the old anchor with its widespreading fixed flukes, with its massive shank and its huge wooden stock. The first successful im-

provement was made when iron movable stocks were introduced. These, however, were first used only with anchors weighing less than 1,500lb. and it was not until 1832 that the British navy extended the use of iron stocks to anchors weighing 3,000lb. In 1847 it was still further extended to 5,600lb., and in 1852, to anchors of 6,000lb.; and now iron stocks are in use with anchors of all sizes and weights. The next important improvement was made by Porter in 1837. His anchor consisted of three main pieces—the crown and arms being one, the shank another, and the stock the third. The oscillatory principle of that anchor was its most remarkable feature, although not entirely new. The crown moved on a bolt in such a way that when one arm was in the ground the other pressed upon the shank. This anchor, subsequently to 1846, passed into provement was made when iron movable stocks was in the ground the other pressed upon the shank. This anchor, subsequently to 1846, passed into the hands of Mr. Trotman, who introduced some modifications of the horn and palm, and now it has been generally adopted in the British service. Other inventions have also been patented from time to time, such as those of Rodgers, Lenox, Mitcheson, Hawkins, Aylen, Cotsell, Hutchens, Morgan and Little's, and many others. Very few of them, however, have stood the test of practical experiment.

The necessity of some new improvement, which should get rid of the heavy and cumbersome stock, was long ago pointed out, and must readily occur to any one familiar with the use of anchors. Cotsell, in any one familiar with the use of anchors. Cotsell, in his standard treatise on ships and anchors (London, 1856), referring to this subject, says: "As the office of the anchor-stock is simply to cant the anchor when the arms are lying flat on the ground, the imposition of any further duty is foreign to its purpose, ill-advised, and highly objectionable. With the present advance of mechanical knowledge, we may with home to see an anchor of simple construcwe may yet hope to see an auchor of simple construc-tion, and at the same time efficient, that shall require no stock. For my own part, I see no reason why this object may not be accomplished." The same author afterwards refers to several attempts to do away with the stock, which had not been attended with success, but repeats his conviction that the desired end would yet be obtained.

desired end would yet be obtained.

Now, thirteen years after the language we have quoted was written, an American appears with a new anchor which meets entirely the advantages suggested by Cotsell in a remarkably novel, yet simple and effective way. It is Mr. Frederick Wittram, of California, but a native of New York, and now residing in the latter place. Mr. Wittram's anchor is covered by Letters Patent in the United States and throughout Europe. It seems to us, beyond a doubt, the most ingenious and effective anchor ever introduced, and is likely to entirely supersede all other anchors now in use. As Mr. Wittram's anchor is so entirely different from all others, we have inserted the accompanying engraving showing

two different views of it. As will readily be noticed there is little to suggest the old time-honoured anchor which, under slightly varied forms, has been in use for hundreds of years, and has symbolized for

to foul, or in the event of a ship grounding upon her anchor, for her bottom to be injured, which frequently occurs when the common anchor is used. Fig. 2 represents the anchor as it appears when catted at the bow of the vessel, and hung by the ring in the crown, having both its flukes concealed within the body of the shank, or as it also appears when stowed. when stowed.

This anchor has been thoroughly tested, both in

This anchor has been thoroughly tested, both in its working and holding capacity, and has been approved of by many officers of the navy, and also by many masters of the merchant service. It does not drag or foul, it is without a stock, will not injure the bows in weighing, catting or fishing, and can be as compactly stowed as a log of wood of the size of the shank. Its many advantages over other anchors were demonstrated in various trials at San Francisco. as compactly stowed as a log of wood of the Size of the shank. Its many advantages over other anchors were demonstrated in various trials at San Francisco and in New York Bay. In both cases a 1,100lb. anchor was used. The experiments at New York were under the supervision of Mr. Charles H. Haswell. It was proved that the same grappling power is attained with 33 1-3 per cent. less weight of anchor than in the case of the Admiralty anchor. By dispensing with the stock, 20 per cent. of weight is saved. The anchor has been exhibited to Admiral Farragut, Rear-Admirals Radford, Godon and Thatcher, and other navy officers, and has received their hearty approval. We hope, if this anchor is introduced, America will begin to manufacture her own anchors. Now, seven in ten are imported from England, whence also a large part of our cables come.—American "Army and Navy Journal." our cables Journal."

# Obituary.

WE have to record this week the decease of Mr. John Graham, Chief Coiner of Her Majesty's Mint. This gentleman succeeded the late Mr. Brande, F.C.S., two years since, and therefore his tenure of the office in question has been very brief. Mr. Graham was brother to the present master of the Mint, and unfortunately for himself had very bad health during nearly the whole time he held the appointment of Chief Coiner. His death took place on Monday, the 22nd inst., at his official residence within the Mint. The vacancy thus residence within the Mint. The vacancy thus created places what might be considered an important post and a good salary at the disposal of the Treasury. It is to be hoped that a practical and efficient gentleman will be appointed to fill it. Many improvements are needed in respect of the metallic currency of the kingdom, and it is not improbable that in a few years it may have to be entirely remodelled on some kind of international system. In such case a very considerable amount of responsibility would fall upon Her Majesty's Chief Coiner.

EXPLOSIVE COMPOUNDS.

EXPLOSIVE COMPOUNDS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I was much pleased to read the admirable and exhaustive paper on the above subject read, by Mr. Perry F. Nursey, at the Meeting of the Society of Engineers on the 1st inst., and reported in your paper. I think, however, that some distinction might be made between fulminants or detonators and the simple explosive compounds that produce no effect when fired in the open air, the former being utterly useless for artillery, large or small, while among the latter may be found a perfect substitute for common powder. The manufacture of a successful substitute must not depend upon high chemical knowledge or manipulation, and the compound must be such as to be freely managed by all who are accustomed to the use of ordinary powder, and, at least, not more dangerous, and that shall not foul the barrel. All these qualities are possessed in an eminent degree by the white powder which accidentally bears my name, the name of the original inventor being unknown to me. This powder and its characteristics are referred to by Mr. Nursey in his paper, but I venture to ask space for a few further remarks in support of the safety and power of this compound. It will not explode in the open air, but merely deflagrates, though, when confined, it apparently exhibits at least four times the propulsive strength of the black powder. Indeed, it will do work which it is impossible to accomplish with ordinary gunpowder by any means whatever. As the use of the cartridge is now universal, non-granulation is no objection, while its two principal properties—enormous propulsive power and condensation—would, on its general introduction, reduce the weight and size of firearms and ammunition probably by one-third. In its manufacture, as the simple substances are actually inexplosive, it will be impossible TO THE EDITOR OF THE "MECHANICS' MAGAZINE." in use for hundreds of years, and has symbolized for us the passion of Hope.

Fig. 1 represents the anchor with the flukes thrown out, and as it appears when dropped from the ship and in use. The flukes swing to either side of the shank on large bolts, and at right angles to each other, so that no matter how the anchor should chance to fall, one or both flukes will take hold, while at the same time there are no projections above the shank, as the stock or unused fluke in the old anchor. It is therefore impossible for this anchor

only in such quantities as may be required for only in such quantities as may be required for delivery, and then only become as dangerous as that in common use, but not more so. The fine powder cannot leak out so as to form a train ready to fire the whole mass, and it is also proof against a damp atmosphere. A sample that had been kept in a damp cellar for twelve months, and had apparently become a mass of slime, when dried in warm air, recovered all its former qualities as perfectly as when fresh made. The objections to the introduction of white powder arise from two sources principally—the commercial

all its former qualities as perfectly as when fresh made. The objections to the introduction of white powder arise from two sources principally—the commercial and manufacturing interest and the professors of scientific chemistry. The chemist tells me not to meddle with chlorate of potash—it is so dangerous an explosive; but it is in daily use in large quantities without fear, as, when alone, it cannot explode. The same gentleman tells me that I do wrong to make the mixture mechanically—that I ought to make the three solutions in distilled water, mix them, and evaporate to dryness. The result, according to these instructions, would be a powder that could neither be touched or handled without destructive explosion. When, however, it is made by mechanical means, it is as serviceable and handy as the common black while it does not foul the barrel, but leaves it perfectly dry after any number of discharges. The small carbonaceous debris which may be seen when fired in the open, are either consumed by excessive heat or are blown out at every successive discharge. It has long been observed that a very large portion of black powder is always blown out unconsumed, and which of course has not contributed to the expulsion of the shot. This fact is plainly visible to a person standing immediately behind the rifleman with the sun in his face, as many targets are placed most absurdly due south, as is the case in this town. The black grains may be seen to issue from the muzzle, and afterwards in flame by the

are placed most absurdly due south, as is the case in this town. The black grains may be seen to issue from the muzzle, and afterwards in flame by the surrounding heat, indicating a waste perhaps to the amount of half the whole charge. This waste cannot take place with white powder, which, from its compact form, instantly ignites through its whole mass, and every particle does duty in expelling the shot. From this circumstance alone, considerable economy will be derived from the general introduction of white powder. The sudden ignition of economy will be derived from the general introduc-tion of white powder. The sudden ignition of the whole charge is objected to by practical men, gunsmiths especially, who say, following an erro-neous idea of Sir W. Armstrong, that slow-burning gunpowder is what is required for artillery, both large and small. Sir W. Armstrong, when he began to make wrought-iron coil guns (a mode of manu-facture laid before the public by me four years before the date of his patent), found that the breech of his gun was blown off—in one case, forty varia astern. In the date of his patent), found that the breech of his gun was blown off—in one case, forty yards astern. In consequence of this, he originated the idea of slowing the combustion of the powder instead of increasing the mass of metal. But the aim of the artillerist is length of range and depth of penetration—objects which depend entirely upon initial velocity, and which are attained in the highest degree by the use of white powder. A breech blowing off is a certain indication that a greater amount of solid metal is required behind the bottom of the chamber.

I find that an erroneous idea prevails that I use the same powder for percussion, but such is not the case, for my white powder will only ignite between the hammer and the anvil of a blacksmith's forge, certainly not under the hammer of a gun lock.—I am, Sir, yours, &c.,

HENRY W. REVELEY.

certainly not under the hammer of a gun lock....I am, Sir, yours, &c.,

1, Baker-street, Reading.

[According to Mr. Reveley, after manufacture, white gunpowder "only becomes as dangerous as that in common use, not more so." What Mr. Nursey, in his paper, advocates, and what public safety demands, is a compound possessing the qualities of perfect safety from explosion when being handled or transported, and a power equal or superior to that of gunpowder when confined in space for work. Of course, this view refers to explosive compounds for blasting and quarrying, and is irrespective of their use in firearms. Gun-cotton has proved itself practically applicable to this purpose, and is largely used in sporting cartridges, and we may in time expect to see its use extended to military purposes. Mr. Reveley has satisfied himself as to the usefulness of white gunpowder in this direction, but he has yet to convince the authorities, and satisfy the public on the point.—ED. M. M.]

# A SIMPLE GALVANIC BATTERY.

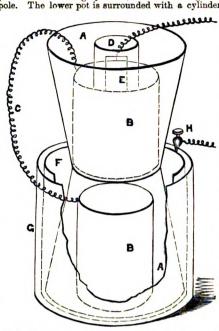

A SIMPLE GALVANIC BATTERY.

SIR,—The accompanying is a sketch of a simple way of making a galvanic battery by means of two ordinary flower pots on the principle you kindly published in the MECHANICS' MAGAZINE for November 13 last. The reason that I trouble you with the above is that your readers may construct for themselves, at a trifling expense, a battery that does away with the use of sulphate of copper in crystals.

does away with the use of A.A. are well cemented crystals.

Two ordinary flower pots A.A. are well cemented together at the base; a free passage, however, being allowed through the holes. The copper solution is divided by a partition or diaphragm having a small aperture as the hole in a flower pot. A dylinder of copper B is placed in each division connected by a copper wire C. The mouth of the bottom pot is covered with a layer or two of moist

bladder, and in the upper one is a porous tube D containing acidulated water and a plate of copper, platinized silver or graphite E, which is the negative The lower pot is surrounded with a cylinder

of zinc F and an outer jar G. H is the zinc or + pole. If a glass tube instead of a porous one, and one end covered with moist bladder be employed, the liberated hydrogen can be seen rising to the surface. I have one constructed in this way working at the present time. 95, Cross-lane, Salford. JAMES HOWARD.

## NITRATE OF SODA.

NITRATE OF SODA.

SIR,—The question, whether the present cost of nitrate of soda can be reduced by improvements in its manufacture, or by diminishing the expense of its conveyance from the nitrate deposits of Peru to the port of shipment, is of importance, not only in connection with the Heaton process, which has been described in your journal, but is also of great moment to the agricultural interest. From having, during many years, been more or less in professional connection with this question, from visits made to the locality, and from having been consulted by the manufacturers and others upon various points relating to the business, I may confidently venture to affirm that the cost to the importer of nitrate of soda may, by improvements in its reduction into commercial form, and by increased facilities of transport, be reduced at least 26 per facilities of transport, be reduced at least 26 per

The natural deposits of nitrate of soda exist chiefly in the vicinity of La Noria, near to the port of Iquique; but such deposits are met with in isolated patches extending over an extent of country computed by the best authorities at fifty square leagues, with an estimated quantity of this mineral of 63,000,000 of tons, so that it may be considered as almost inexhaustible. The crude nitrate, called by the natives "Caliche," is excavated upon the surface of the ground, below which surface it is found from one inch to many feet in depth, the beds varying in thickness from a few inches to several feet. From a paper of William Bollaert, Esq., F.R.G.S., read before the Royal Geographical Society last year, it is stated that about 100 works are in operation, yielding employment to a population of nearly tion, yielding employment to a population of nearly 20,000 souls, and about 15,000 animals; the greater part of which are employed in the transport of fuel and provisions up to the works from the coast, and in conveying down the nitrate for shipment.

The process of manufacture, which consists simply

in separating the salt from the earthy matter with which it is found in combination, is now exceedingly costly, on account of the scarcity of fuel, which has to be brought up from the sea, the mines being situated in a rainless and desert country; while all provisions, fuel, &c., have to be imported and brought up from the coast at an immense expense, brought up from the coast at an immense expense, on account of the roads being merely mule paths winding down the face of the coast range of mountains, which rise here abruptly from the sea to the height of 3,000ft. Previous to the recent earthquakes, the cost of conveyance alone of the nitrate was about £2 3s. per ton; the maximum distance between the mines and the port being only about twenty-three miles. Some years since a railway was commenced from Janieges to Le Narie was commenced from Iquique to La Noria by an was commenced from Iquique to La Noria by an English company, but in consequence of the panic the capital could not be raised, and the works were suspended after several miles of line had been form d, while a variety of schemes have from time to time been contemplated or tried so as to reduce the present great expanse of convergence of the contemplate of the present great expanse of convergence of the present great expanse of the present great e the present great expense of conveyance. The in-convenience in shipping the nitrate by lighters, and

the delays incurred by vessels in loading, have tended to augment considerably the freights. are seldom less than £3 per ton.

At the time (a year or so since) when my investi-gations were made, the cost of reducing the nitrate, its transport down from the mines, and its freight to England, stood about as follows:

Mining and manufacture (not including profit)
Transport to coast £2 19 8 per ton. 20 Shipping expenses . Freight to Europe Expenses in Europe . 5 79 8 0 £8 13 10

The above expenses by improvements in the manufacture (now in all cases but one extremely manufacture (now in all cases but one extremely imperfect), by the formation of a simple and inexpensive line of tramway from Iquique to the mines, and a mole accommodation for the shipping to load alongside, I have no hesitation in stating may most readily be reduced as follows:—

By improvements in manufac-ture, diminishing cost of fuel,

&c. £1 5 0 perton. transport ditto By improvements in shipping . Ditto ditto freights . 0 3 6 0 5 £2 11

So that, irrespective of the manufacturer's and importer's profits, the nitrate should be deliverable in England at £6 2s. 4d. per ton, instead of

in England at £6 2s. 4d. per ton, instead of £8 13s. 10d., as at present.

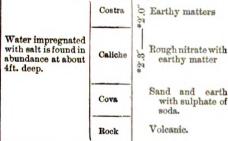

A railway, suitable for the above country, would certainly not cost more than £250,000, and as the shipments of nitrate from this district of Peru have some years exceeded 100,000 tons, the above saving of 51s. 6d. per ton should more than pay for the railway in one year; while for the rate of conveyance by railway I have, notwithstanding, allowed, as above, the very large one of about one shilling per ton per mile.

above, the very large one of about one shilling per ton per mile.

In addition to the above, I may remark, that recent advices from the Pacific inform us that deposits of nitrate of soda have been discovered in the extreme north of Chili, at La Chimba, only five or six miles from the coast; and if such be the case, as I am assured it is, the present cost of nitrate of soda may be still further reduced, at least one pound per ton.—I am Sir yours &c.

soda may be still further reduced, at least one pound per ton.—I am, Sir, yours, &c.,
WILLIAM LLOYD, Civil Engineer.
2, Dartmouth-street, Westminster, S.W.
February 17.
P.S.—Through the kindness of Mr. Bollaert, I am enabled to append the following section of the nitrate beds:—

SURFACE OF PLAIN.

Mr. Bollaert also states that the formation of a railway would dispense with the employment of nearly the whole of the animals now employed; and if we take only half the number as rendered unnecessary, or 7,000 animals at 3s. per diem for 300 days, the saving in this respect alone would exceed

hecessary, or 7,000 animals at 3s. per diem for 300 days, the saving in this respect alone would exceed £300,000 annually.

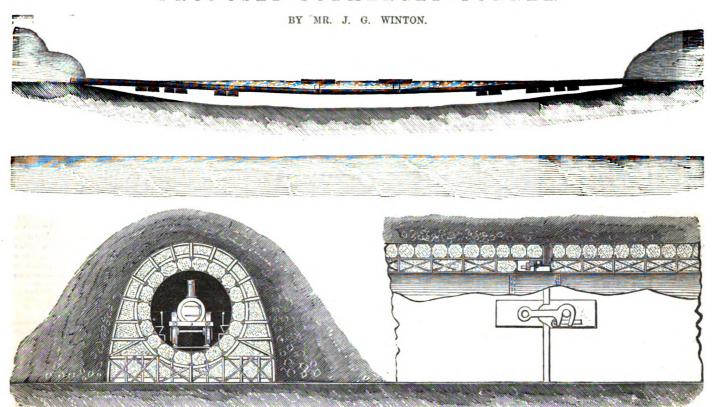

With regard to the benefits which might be derived by the agriculturists of England, I may quote from Mr. Puscy's paper in the "Journal of the Royal Agricultural Society," 1853:—"It has been proved that nitrate at its present high price can compete successfully with guano as a manure for our corn crops. It is wonderful, certainly, to have found a mineral which at the present high price (then stated to be over £16 per ton) yields us wheat at a cost of 24s. a quarter, and if cheapened, as it apparently might be, by one-half, would of course yield it at 12s. per quarter. Thus, instead of 3,000,000 quarters of wheat, costing £6,000,000 sterling, we might import yearly 200,000 tons of nitrate, costing little more (at £8 per ton) than £1,600,000 only, and so our farmers might obtain from their own farms the whole foreign supply of wheat without labour, and with but a few months' outlay of capital." outlay of capital."

# DEFLECTING ARMOUR-PLATES.

DEFLECTING ARMOUR-PLATES.
SIR, - In reference to a paper read at the Royal
United Service Institution, on the above subject, by
Mr. J. M. Hyde, and reported in your last issue,
permit me to call your attention to the fact that the
principle of deflecting armour-plates for throwing

#### PROPOSED SUBMERGED TUNNEL.

off shot and shell from the sides of vessels, was brought forward, through the Society for the Encouragement of Arts, Manufactures, and Commerce, about the year 1823-4. Reference to the Society's Transactions of about that date would, no Society's Transactions of about that date would, no doubt, bring out the history of the case. I recollect being in England at the time, and I believe I was present at the discussion on the model produced. No doubt the details would be found to differ, as armour-plates, as now made, were unknown at that period; but the principle is identical, and was partially adopted during the late American war.—Jam, Sir, yours, &c.,

HENRY W. REVELEY.

1, Baker-street, Reading, February 24.

SUBMERGED TUNNELLING.

SUBMERGED TUNNELLING.

SIR,—Some time back you noticed my proposal for tunnelling across the English Channel, with a submerged tunnel, a structure of wrought iron, filled in with concrete, constituting the proposed work. For an undertaking of such magnitude, I proposed to form the tunnel for two sets of rails, having a railway on the top of the structure, with small cast-iron wheels fitted to the bottom of each portion. Thus, when the shore tube was sunk, another could be sunk over it. Each section would thus be run down on the structure itself, and, with a suitable pontoon, lowered until it rested on the bed of the Channel. A temporary joint could thus be made with an hydraulic ring, or simply a ring of metal, pressed against an elastic medium, with a number of set screws, just similar to the packing ring of a slide valve, with suitable temporary bulkheads. A communication would then be opened up at the ends of the tubes, and the structure could be heads. A communication would then be opened up botted and riveted together permanently. I likewise considered the work should be covered over with a bank of loose stones, run down in a large truck, and emptied over the tube. In course of time, this bank would become quite compact with the natural deposit, &c. Probably a layer of stiff clay would form the best covering for the tube, in combination with the loose stones, over all. Covering the tube would be a work of time, and would in nowise interfere with the traffic through the tunnel. the tube would be a work of time, and would in nowise interfere with the traffic through the tunnel.
For shorter distances, say, two miles, I consider it
could be sunk in mass. For shallow rivers, &c., I
would form the tube for only one set of rails; thus
greater depth of water would be secured overhead;
each portion could be floated on suitable pontoons,
then jointed together with an india-rubber ring,
firmly passed into a recess in the end of one tube,
having a circular projection from the adjacent tube.
On the outside, the tubes would pivot on a centre,
secured together with strong clasps. Thus, when
the stream was bridged across, water would be let
into the pontoons at the centre, and then the structure would sink. The pontoons could then be
withdrawn, the water pumped out, and, with suitable
chains, the structure could be supported from above,
as shown in the accompanying sketch. Thus the as shown in the accompanying sketch. Thus the remainder could be removed, and placed overhead,

so as to support the mass. The chains would then be lowered, until the structure rested on the bed of the stream or arm of the sea to be crossed. By this means, communication could at once be opened up from shore to shore. Of course, a permanent joint would be made with wrought-iron plating, and the back of the plate filled in with concrete. Any number of such tubes could be laid side by side, and then covered over with a sufficient depth of rubble, clay, &c. Smaller tubes, say, \$ft. internal diameter, could securely be adopted for conveying a number of submarine telegraph wires in certain situations.—I am, Sir, yours, &c.,

18, Gladstone-street, February 18.

SMITH'S LIQUID FUEL FURNACE.

SIR,—As regards your foot note to my letter on the above subject, which you inserted in the last number of the MECHANICS' MAGAZINE, permit me to observe that the owners of Messrs. Wise, Field. and Aydon's patents, who have from time to time given due notice to infringers, are now acting under advice, and will be found fully prepared, when the proper time arrives, for taking farther steps.—I am, Sir, yours, &c., W. LLOYD WISE.

Chandos Chambers, Buckingham-street, Adelphi, February 25.

#### TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 is. 8d. yearly, or 10s. 10d. half-yearly, payable in

of £1 is. 8d, yearly, or 10s. 10d. half-yearly, payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications anaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

#### Meetings for the Baeek.

Mon.—Royal Institution.—General Monthly Meeting, at 2 p.m.
Society of Engineers.—Mr. E. G. Bartholomew on "Electric Telegraphy." There will be a Ballot for the Election of New Members, at 7.30 p.m.

Tues.—Royal Institution.—Rev. F. W. Farrar on "Comparative Philology," at 3 p.m.

The Institution of Civil Engineers.—Mr. Imrie Bell,
M. Inst. C.E., on "Sinking Wells for the Foundations of the Piers of the Jumna Bridge, Delhi Railway;" and Mr. John Milroy, Assoc. Inst. C.E., will give a "Description of Apparatus for Excavating the Interior of, and for Sinking, Iron Cylinders," at 8 p.m.

Thurs.—Royal Institution.—Dr. John Harley on "Respiration," at 3 p.m.

Fri.—Royal Institution.—Mr. Huggins on "Some Further Results of Spectrum Analysis Applied to the Heavenly Bodies," at 8 p.m.

Sat.—Royal Institution.—Professor Odling on "Hydrogen and its Analogues," at 3 p.m.

## Rabal, Military, and Gunnery Items.

SMALL steamers are shortly to ply on the large lake of the Bois de Boulogne, making the circuit twice for 25 centimes.

HER MAJESTY has conferred on Admiral Sir George Rose Sartorius the rank of Vice-Admiral of the United Kingdom. Sir George Sartorius is one of the few survivors of the battle of Trafalgar.

A TELEGRAM from Trieste conveys the melan-choly intelligence that the well-known Austrian frigate, "Radetzki," has been blown up in the Adriatic, and that 300 persons were killed by the dreadful explosion.

It is reported that the saving which [Mr. Childers will propose to effect during the financial year of 1869-70 will be from £900,000 to a million sterling. It is expected that the saving in the army estimates, which are now nearly completed, will be something over one million sterling. over one million sterling.

THE French jurors of the French Exhibition at THE French jurors of the French Exhibition at Havre have awarded the bronze medal for steering apparatus to Mr. Henry Skinner, of London, for his vertical screw, which does away with the tiller and all the heavy gear now in use, as it is fixed in the rudder head, and requires only one man at the wheel in the very worst of weathers, and is besides most simple and impossible to get out of order.

simple and impossible to get out of order.

An Admiralty circular has been received at Woolwich Dockyard informing the officials that Capt. Robert Scott, R.N., has been appointed Superintendent of Gun Carriages for the Royal Navy. The conferring of this appointment at the present time seems to mark their Lordships' approval of Capt. Scott's services in constructing the new 18-ton gun carriage, the firing from which during the trial of Her Majesty's armour-clad ship. "Hercules" in her six hours' run off the Isle of Wight was conducted so successfully. was conducted so successfully.

Following the example set by France and Norway, at Boulogne, Havre, Arcachon, and Bergen, the first maritime exhibition will be held in the autumn of the present year at Naples. This exhibition, which will be international, presents an im-

portant field for British exhibitors of naval appliances, as Italy, from her geographical position, is not unlikely to become a great maritime power, This exhibition, as that of Havre, will embrace all apparatus and implements used in fishing, pisciculture, and fish curing, and will include ship stores and rewisions &c. and provisions, &c.

THE Prussian screw (armoured, iron) frigate "King William" made a trial of its speed over the measured mile, off the Maplin Sands, on Monday week, and mile, off the Maplin Sands, on Monday week, and attained a mean speed, under full boiler power, of about 14½ knots per hour. The "King William" was designed by Mr. E. J. Reed. The trial was conducted under precisely the same conditions that would have been observed on the trial of one of Her Majesty's ships over the measured mile in Stokes Bay, Nixon's steam navigation coal only being burnt in the furnaces, and the fires being in the exclusive charge of the same men who perform those duties on all important trials of Her Majesty's ships on the Stokes Bay mile—the stokers from the steam factory of Portsmouth Dockyard. from the steam factory of Portsmouth Dockyard.

The annual meeting of the Marine Society was held on the 4th inst., at the offices in Bishopsgate-street, the Earl of Romney, president, in the chair. By the report of the committee for the past year, it By the report of the committee for the past year, it appeared that during the twelve months ending December 31, 1868, 308 poor boys had been received on board the society's training ship "Warspite" at Woolwich, of whom 97 had been sent into the Royal Navy, and 187 to the merchant service. The complement of boys on board the "Warspite" had been kept up at 150 (this has since been increased to 160). We call the attention of all benevolent persons to the good which is being effected by the Marine Society in receiving so many hundreds of destitute boys and training them for employment in the sea service. the sea service.

FROM a communication transmitted to the Senate by the American Secretary of War, on January 20, it appears that during the year 1868 the Ordnance Department purchased 18,000 Sharp's rifles at 4 dollars 50 cents each, amounting to a total of 81,000 dollars; two 12-inch rifle-guns at 6,500 dollars each; one 3-inch wrought iron breechloading gun, for 3,291 dollars 75 cents; 394 12-pounder rifle shells for 2,470 dollars; ten 12-inch rifle (500 pounds) shot for 360 dollars 24 cents; forty-five 12-inch chilled shot for 2,979 dollars 31 cents; ten 13-inch (318 pounds) spherical steel shot for 1,113 dollars, and six 12-inch conical steel shot (615 pounds) for 1,291 dollars and 85 cents. The rifle shot cost 6 cents, and the chilled shot 5-975 cents per pound, and the steel shot 35 cents a pound. They also contracted for a 3-inch breechloader wrought iron rifle gun, one 10-inch rifle gun at 5,600 dollars, and two 12-inch for 6,500 dollars each, and one 20-inch Rodman gun for 28,000 dollars. FROM a communication transmitted to the Senate

### Miscellanea.

THE President of the Royal Society will give conversaziones on Saturdays, March 6 and April 24, at Burlington House, Piccadilly.

A CORRESPONDENT of the "Field" says:—On December 22, I gathered a fairly ripe strawberry, Ambrosia—it has been covered with a broken tumbler (glass)—and a bloom of "clematis azurea grandiflora."

THE chestnut tree in the garden of the Tuileries, called Le Vingt Mars, has this year anticipated, by more than a month, the usual time for putting forth its blossoms, as several are already in full bloom.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending February 20, was 5,004. Total number since the opening of the Museum, free daily (May 12, 1858), 1507,027

An advanced night school is about to be opened at the South London Working Men's College, 91, Blackfriars-road, for arithmetic, mensuration, and gram-mar, on Monday, Wednerday, and Friday evenings. Application for entrance to be made to the secretary, at the College.

An important discovery of coal has been made at Argenta, in California, situated about \$70 miles from Sacramento. This coal is said to be of excellent quality, and will, no doubt, be of great service to the American steamers that run from San Francisco to China and Japan.

THE demand in the iron trade for rails has been so THE demand in the iron trade for rails has been so large of late, that it is stated all the works, both in Wales and the north of England, are full of orders up to September next. The requirements are principally for Russia, but Austria and Hungary are likewise taking good quantities. In the other branches of the trade there is not the same activity.

Among the cabin passengers just arrived from New York, by the steamship "Columbia," was Miss Anna Swan, a native of Nova Scotia, but of Scotch descent, who is en route to London and Paris. Miss Swan is stated to be 8ft. lin. in height, and stout in

proportion, weighing about 400lb. She is 21 years age, prepossessing in appearance, has a cultivated mind and engaging manners.

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending February 20, 1869, was—on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 16,677; Mevrick and other galleries, 3,080; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,861; Meyrick and other galleries, 242; total—21,860. Average of corresponding week in former years, 10,442. Total from opening of Museum—8,176,290.

THE statistics relating to mining in Prussia show the surprising progress made by that country during years in this industry by the introthe last twenty years in this industry by the intro-duction of improved systems of extraction by the use of steam power. In 1837 there were 1,587 mines worked in Prussia, giving employment to 33,161 miners. In 1867 this number had increased to 2,162, with 48,351 miners. The total value of the mineral production, which in 1837 was £833,932, in 1867 amounted to upwards of £8,565,000.

A NEW gold-field has been discovered in Strath A NEW gold-field has been discovered in Strath Brora, Sutherlandshire. On Saturday week, a few diggers started work in Gordonbush Burn. The quantity of gold got by each is stated to have averaged from five to twenty-five grains. The quality of the gold is equal to that found at Kildonan. Owing to the flooded state of the burn and the stormy weather, nothing was done on the following Monday, but a number have since been working during the fine weather. during the fine weather.

A COURSE of free popular and scientific lectures. including dramatic readings and recitals, is in course of delivery at the Crystal Palace every Monday, Wednesday, and Thursday. The inaugural lecture was by Dr. Thomas Wood, F.C.S., a gentleman of recognized scientific attainments, on a "Bottle of Colon Western Colon Parameters, and the Colon Parameters Soda Water, its Properties and Manufacture." The subject was very skilfully handled by Dr. Wood, and interspersed with a variety of chemical experiments, affording not only considerable amusement, but a fund of useful information to a large and appreciative

The widow and daughters of the late M. François Delessert have offered to present to the Institute of France the magnificent botanical library formed by the brothers Benjamin and François Delessert, on the brothers Benjamin and François Delessert, on condition that it is placed in a separate apartment, with the title of the Bibliotheque Delessert. This magnificent scientific library, the finest of its kind, perhaps, in France, comprises about 8,000 volumes, and the present possessors desire to carry out the views of the collectors, and preserve it entire in the interest of science, a wish which the Academy of Sciences will doubtless be eager to carry into effect.

A NOVEL form of mutual life assurance has been proposed among the persons employed in the banking establishments of New York. All may join, irrespective of health or age, and the subscription is to be a dollar. When a member dies the whole of the money in hand is to go to his family, and a new subscription of a dollar is to be made, to go in like manner to the heirs of the next deceased. The inequality of the benefit from the fact that the best lives would be taxed to insure the feeble and infirm lives would be taxed to insure the feeble and infirm would give the plan a charitable rather than an economical character, but in that shape it would, of course, relieve many cases of temporary distress.

course, relieve many cases of temporary distress.

At the monthly general meeting of the Zoological Society, held at the Society's house, Hanover-square, the Viscount Walden, president, in the chair, the Baron de Teissier, Captain Charles George Fane, R.N., Mrs. Turner, and Messrs. Charles Langford Oliver, Ernest Thomas Hankey, John Bridge, Alexander F. Cuningham, E. Breedon, Charles Horne, Stephen Busk. Frank Evans, and C. R. Wilson were elected Fellows; and Mr. John Denis Macdonald, surgeon, R.N., F.R.S., a corresponding member of the society. Thirty new candidates for the fellowship were proposed, and ordered to be balloted for at the next meeting of the society. The number of visitors to the society's gardens in the month of January was stated to have been 15,311.

THE American cotton crop of 1868 is officially THE American cotton crop of 1868 is officially estimated at 2,380,000 bales—viz., North Carolina, 140,000 bales; South Carolina, 180,000 bales; Georgia, 290,600 bales; Florida, 35,000 bales; Alabama, 35,000 bales; Mississippi, 400,000 bales; Louisiana, 250,000 bales; Texas, 260,000 bales; Arkansas, 265,000 bales; Texas, 260,000 bales; and other States, 75,000 bales. The department estimate for 1867 was 2,340,000 bales, while the actual receipts proved to be 2,450,000 bales. The estimate for 1866 was 1,835,000 bales, while the actual receipts were about 1,900,000 bales. The actual receipts were about 1,900,000 bales. The American cotton-growing interest is thus slowly recovering from the effects of the civil war of

AT the establishment for the breeding and preservation of fish at Concarneau, there are six reservoirs in the open air, with a surface equal to about 1,200 square yards, and depths varying from two to four yards, and these are supplied twice a day with fresh sea-water by means of grated flood-gates which prevent the escape of the fish. At one

extremity of these reservoirs is a large building extremity or these reservoirs is a large building containing seventy aquariums or tanks, supplied by a continual stream of sea-water, containing a vast number of fish, crustacea, and mollusks, whose forms, colours, and habits may be studied without difficulty. This is an admirable establishment for the purpose intended, and appears to be well adapted for the furtherance of abstract and practical science in connection with the creatures of the

OUR readers will doubtless remember that the man Moosa, who deserted Dr. Livingstone and reported that he had been killed, was handed over to the that he had been killed, was handed over to the Sultan of Johanna for such punishment as might be deemed necessary. Having undergone eight months' imprisonment in irons at Johanna he was, in No-vember last, sent down to Zanzibar to Dr. Kirk, Her Majesty's acting consul there, for further punishment or liberation. Dr. Kirk, writing to the Bombay government, states that in reply he informed King Abdulla's agent that his Highness had, by the punishment inflicted on Moosa, anticipated the wish punishment innicted on Moosa, anticipated the wise of Her Majesty's government, and that now it would be his duty to set Moosa free, but as one banished from his native land. Dr. Kirk assured the Sultan's envoy that Her Majesty's government would receive with much satisfaction the assurance of friendship shown by his having made an example of one had caused so much grief and anxiety through his cowardly flight and base lies. He set the prisoner Moosa at liberty, but cautioned him not to return to Johanna without the Sultan's permission.

## Natents for Inbentions.

#### ABRIDGED SPECIFICATIONS OF PATENTS

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

warned not to produce them without an acknowledgment:—
BOILERS AND FURNACES—2409, 2412, 2424, 2451
BUILDINGS AND BUILDING MATERIALS—None.
CHEMISTRY AND PHOTOGRAPHY—None.
CULTIVATION OF THE SOIL, including agricultural implements and machines.—2444
ELECTRICAL APPARATUS—None.
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2431, 2441, 2450, 2460, 2465
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2411, 2421, 2428, 2435
FURNITURE AND APPAREL, including household utensila, time-keepers, jewellery, musical instruments, &c.—2447, 2459, 2463
GENERAL MACHINERY—2430, 2446, 2449, 2450, 2457
LIGHTING, HEATING, AND VENTILATING—2445, 2464
METALS, including apparatus for their manufacture—2417, 2418, 2439, 2453, 2461
MISCELLAREOUS—2408, 2410, 2413, 2414, 2415, 2416, 2427, 2423, 2425, 2426, 2432, 2434, 2438, 2443, 2448, 2456, 2467, 2466, 2467
ROADS AND VEHICLES, including railway plant and carriers.

2466, 2467
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2429, 2433
SHIPS AND BOATS, including their fittings—2407, 2427, 2437, 2442, 2454
STEAM ENGINES—2420, 2458
WARFARE—2419, 2435, 2436, 2452

2402 F. A. LEIGH, Lancaster. Carding engines. Dated July 31, 1868.

This consists, in the first place, of an arrangement for effecting the enclosure of the licker-in. The patentee uses end shells, cast or otherwise formed in two pieces, one piece of each shell being formed on the pedestal in which the shaft of the licker-in revolves, the other piece being formed on the cap of the pedestal, the two portions forming a complete circle. The licker-in cover is fitted to the upper portions of the end shells, and the under guard or casing to the lower portions, the cover being connected by an intermediate V-shaped plate with the fly plate that guards the main cylinder, thus preventing to a great extent the discharge of fly from the carding engine. In carding engines having a flexible bend, the patentee makes the bend of sufficient length to sustain the fly plate. Another improvement consists in mounting the brackets or arms which carry the grinding roller upon the bosses formed on the pedestals around the bearings, so that each of the arms can be swivelled to some extent around the centre of motion of the licker-in, and be fixed by means of a set screw in the position required.—Patent completed.

2403 J. BATCLIFFE, Lancaster. Engines. Dated July 31,

2403 J. BATCLIFFE, Lancaster. Engines. Dated July 31,

The main object of this invention is to increase the power of steam engines and all other motive power ma-chines, by an arrangement or combination of cranks of unequal stroke, and levers or arms of unequal fulcrum. The crank of the first motion shaft is connected to a double The crank of the first motion shaft is connected to a double lever, free to oscillate on a ball formed on its centre; as the crank revolves, the lever follows its course, and causes another wheel at the other end to revolve likewise. This wheel gears into another wheel, the axle of which is fitted with a crank; this crank operates a second lever in the same manner as the first, any number of cranks, levers, and wheels may be employed.—Patent completed.

2404 A. G. DAY, Seymour, U.S.A. Imitation india-rubber. Dated July 31, 1868.

This consists in combining certain acids with the in-

gredients which compose the compound for the purpose of enabling the oils employed to better combine together. For a compound adapted for soft or elastic rubber goods, the patentee takes, when steam heat is to be employed for vulcanization, 201b. of linseed oil, 201b. of blcarbonate of soda, 11b. of nitrate of soda, 15lb. of coal tar, 51b. of asphaltum, 51b. of litharge, 21b. of calcined magnesia, and 81b. of sulphur. If dry heat is to be used for vulcanizing, the following mixture is employed:—201b. of linseed oil, 201b. of cotton seed oil, 41b. of coal oil, 30oz. of sulphuric acid, 21b. of bicarbonate of soda, 11b. of nitrate of soda, 15lb. of coal tar, 51b. of asphaltum, 41b. of litharge, 11b. of calcined magnesia, and 81b. of sulphur. For what are termed semi-hard rubber goods, the patentee employs 241b. of linseed oil, 161b. of cotton seed oil, 41b. of castor oil, 12oz. of sulphuric acid, 12oz. of nitric acid, 11b. of blcarbonate of soda, 11b. of sulphur and 11b. of calcined magnesia. For hard rubber goods, the mixture consists of the following:—321b. of linseed oil, 81b. of cotton seed oil, 31b. of castor oil, 11b. of coal oil, 24oz. of nitric acid, 6oz. of muriatic acid, 41b. of coal oil, 24oz. of nitric acid, 6oz. of muriatic acid, 41b. of bicarbonate of soda, 21b. of muriate of tin, 31b. of coal tar, 51b. of asphaltum, 11b. of gutta-percha, and 101b. of author.—Patent completed.

2405 J. F. LACKERSTEN, Cannon-street. Preserving food. Dated July 31 1868. gredients which compose the compound for the purpose 2405 J. F. Lackerstren, Cannon-street. Preserving 2405 Dated July 31, 1868.

For this purpose the reference 2405 Preserving 24

2405 J. F. LACKERSTEN, Cannon-street. Preserving food. Dated July 31, 1868.

For this purpose the patentee employs a receptacle in which is placed the substances required to be preserved, through an opening provided with a door or cover, which, when closed, forms a tight joint, and thereby, in a manner, hermetically seals the receptacle, to which are applied suitable safety and pressure gauges. In connection with such receptacle, an apparatus is employed for generating carbonic acid gas. Two strong vessels provided with suitable covers are made of any desired material and strength; these vessels are connected together at their lower parts by a pipe or tube, and at their upper parts by another pipe or tube, to which a stop cock is applied in order to cut off the communication between the upper parts of such vessels when required. In one of these vessels any suitable acid (sulphuric acid by preference), the level of the acid, when not acting on the carbonate, being maintained at a point slightly below the bottom of the carbonate. Another pipe passing from the upper part of the vessel in which the carbonate is placed dips into a vessel containing water, the upper part of such vessel, above the water level, being connected to the safe by a pipe or way having a stop cock applied thereto.—Patent completed.

2406 P. N. J. NARCISSE, Paris. Feeding botters. Dated July 31, 1868.
